

Editor's Comment:

The revised manuscript on "Investigating prevalence rate of HCV, HBV, and HIV co-infection in Khorramabad, Iran, in 2013" has too many errors.

Line 18 should read this cross-sectional study was designed in 2013

Line 33 should read Using chi-square test, a statistically significant relationship was detected between hospital care of patients and prevalence of co-infection.

The major flaw in this manuscript is the existence of less than 5 observations in **seven cells in Table 1**. The assumption of Chi-square statistics is violated. The authors should perform only frequency analysis

The sample size is too few.

This study should be revised and rewritten.

Authors Feedback:

Thank you for your comments

1-The sentences of lines 18 and 33 were revised.

2-Could you explain more clearly the observations in the table. The observations in Our Articles is seven.

3-In this study, all comparisons were performed by chi-square test. If necessary, you know that the testing was eliminated, in this case comparisons are based on a single frequency. If you think this is an acceptable way to remove test.

4-There is no possibility to change the sample size because this study was done a year ago.
