# <u>Original Research Article</u> A MODEL FOR CALCULATING THE MACHINING

## TIME OF A LASER CUTTING MACHINE

4

## 5 Abstract

6 Laser cutting machine cuts a given profile with precision and accuracy that cannot be compared with other CNC cutting machines. This is made possible because the laser cutting beam forms a 7 thin kerf of about 0.15 mm during the cutting process. The heat affected zone (HAZ) on the 8 material is also minimal. One of the commonly asked questions by our clients is, "how long 9 would it take to cut this profile." The inability of the cutting software to predict the machining or 10 cutting time becomes a challenge for the operator. In this paper, a model was developed relating 11 12 speed and profile length to machining time. The actual machining time of five different profiles were obtained from the HG LCY 300 laser cutting machine and compared to the calculated 13 machining time obtained using the model. By comparison, the slight differences between the 14 15 actual and the calculated machining time are just in milli-seconds; this suggests that the model 16 is valid and can be employed by laser cutting machine operators to predict the machining time for profiles to be cut even before cutting process commences. 17

18 **KEYWORDS**: Laser cutting, Profile length, Machining time, cutting software, Model

### 19 Introduction

Over the past decade, laser cutting has developed into a state-of-the-art technology. It is estimated that more than 25,000 cutting systems are used for the high-power cutting of metals and non-metals worldwide [1]. Laser cutting machines are used in workshops for cutting materials, especially, mild steel which is predominantly used in the laser cutting industry [2].

A high intensity beam of infrared light is generated by a laser cavity; this beam is focused onto 24 25 the surface of the work piece by means of a lens, the focused beam heats the material and 26 establishes a much localized melt (generally smaller than 0.5 mm in diameter) throughout the depth of the sheet. The molten material is ejected from the area by pressurized gas jet acting 27 coaxially with the laser beam; with certain materials, this gas jet can accelerate the cutting 28 process by performing some chemical as well as physical functions (for instance, the oxidation 29 process initiated by cutting carbon or mild steel in a jet of pure oxygen generates its own heat 30 31 and this substantially improves the efficiency of the process). The localized melt is extended across the surface of the sheet thus generating a cut [3]. 32

The cutting speed and *assist gas* control the cutting process while laser pulse width, frequency and discharged current control the beam quality; CNC 2000 software coordinates the beam and the process parameters. By contour cutting 2-D thin sheet parts, the use of machines with X-Y coordinate is effective and real when CNC control unit is used; it is often a multi-axis mechanical system which permits linear movements. The CNC is claimed to be superior to the types conventionally used in the manufacture of machine tools. It is up to 10 times faster, compensates for overrun errors, adapts the programmed laser power to the processing speed, and controls the assist gas pressure and the laser parameters. CNC laser-cutting machine offers an optimal solution to cut all kinds of sheet materials economically [4].

The assist or cutting gas helps in cooling the work piece, clearing the fines off the cutting path 42 and raising the exothermic reaction of the cutting process. The type of gas chosen depends on the 43 reactive nature of the material being cut: molten thermoplastics do not chemically react with 44 nitrogen or oxygen and so compressed air can be used as the cutting gas.  $CO_2$ , on the other hand, 45 are usually a cheaper production route and are therefore favoured for general engineering 46 purposes because are not reactive with a wide range of materials ranging from metals to 47 polymers and wood. Molten stainless steel reacts with oxygen but not with nitrogen and so 48 nitrogen is used in this case; on the other hand, molten titanium reacts with oxygen or nitrogen 49 and so argon, which is chemically inert, is used as the cutting gas [3]. 50

Laser is a beam with high brightness, high power and very good direction, thus, laser cutting excels in applications requiring high productivity, high edge quality and minimum waste, due to the fast and precise cutting process [5, 6].

The laser machines used in workshops are of CLASS 4 type; the light this laser system produces, whose wave length is close to infrared light, is invisible, therefore, more attention needs to be paid to safety protection when using it in the work place [7, 8, 9].

Laser cutting machine cuts a given profile with precision and accuracy that cannot be compared with other CNC cutting machines; this is made possible because the laser cutting beam forms a thin kerf of about 0.15 mm during the cutting process. The heat affected zone (HAZ) on the material is also minimal because of the thin kerf and the *assist gas* used [10, 11, 12]. The laser cutting technology has actually made industrial cutting of mild, silicon and carbon steel plates easy since the profile can be drawn on CAD software and imported to the laser cutting machine for implementation.

The inclusion of machining time in the cutting software of the laser cutting machine would make its features complete and excellent. In this work, we developed a model for calculating the machining time of the laser cutting machine using the HG LCY 300. This became necessary because of the need to establish or predict machining/cutting time, even before the cutting process begins, based on our customers' demand in order to improve the value of the machine.

#### 69 Methodology

70 The resolution of the stepper motors used for the worktable is first determined by cutting out a 71 circle of radius 20 mm on a 2 mm thick mild steel plate and taking the machining or cutting time 72 at different speeds. A relation is then established to convert the profile length to number of revolutions using the stepper motor's resolution obtained. The machining time is then obtained 73 74 as a variable that depends on the cutting speed, profile length and stepper motor's resolution. The last step was to carry out validation test of the model. The profile samples were drawn on CAD 75 software and imported to the laser machine; the cutting process was observed on the monitor, the 76 cutting time was also monitored and recorded as actual machining time when cutting was 77 completed. Five different profiles/samples were cut at selected speeds and their actual machining 78 79 times were recorded; the calculated machining times were also obtained using the model. The results obtained for actual and calculated machining time were tabulated and compared to see the 80

81 extent to which the model is valid.

#### 82 **Resolution of the stepper motor**

There are two stepper motors attached to the worktable, the movement of the table in both x and 83 y axes are carried out by each of these motors [9] and can move 500 mm in both directions. The 84 cutting speed is selected on the parameter settings of the CNC 2000 software, the effect of which 85 86 is seen on the table. If a cutting speed is selected to cut a particular profile on work pieces of different thickness, the machining time will be the same. For instance, if the beam parameters are 87 88 set to cut a 2 mm mild steel plate at 40 rev/min, a 3 mm mild steel plate can also be cut at 40 rev/min if the parameters are raised higher. The resolution of the stepper motor (R), which is 89 constant is what makes this achievable. 90

To get the resolution R of the stepper motor, the following data were taken while cutting out a circular profile of radius 20 mm from a 2 mm mild steel plate:

- 94 Fig 1: Profile sample
- 95
- 96 Profile length =  $\pi D = 125.66$  mm
- 97 Table 1: Machining time for cutting profile sample

Speed (Rev/min)	Actual machining time (s)
60	126

120	63
180	42
240	31

- 99 Relating machining time to profile length and number of revolution
- 100 From table 1, at 60 rev/min,
- 101 The stepper motor moves the worktable over a linear distance of 125.66 mm for 126 seconds;
- 102 This implies that the worktable moves a linear distance of 0.9973 mm for 1 second.
- 103 <mark>Also,</mark>
- 104 the stepper motor makes an angular movement of 60 revolutions in 1 minute;
- 105 which also implies that the stepper motor makes an angular movement of 1 revolution in 1
- 106 second.
- 107 Therefore, the angular movement of 1 revolution of the stepper motor in 1 second translates to a
- 108 linear movement of the worktable over a distance of 0.9973 mm.
- 109 This is the resolution 'R' of the stepper motor.

#### 110 **Converting profile length to number of revolution**

Since the profile length is determinable, there is need to convert it from linear value to number of revolutions made in cutting the profile. Using the deduction made from the resolution of the stepper motor, we can conclude that,

- Since 1 revolution of the stepper motor translates to a movement of the worktable over a linear
   distance of 0.9973 mm;
- then, X revolution of the stepper motor will translate to a linear movement of the worktable
   equivalent to a 'profile length' of Y mm.
- 118 Therefore, cross multiplying gives,
- 119 X rev =  $\frac{profile \ length}{0.9973}$  .....(1)
- 120 where X is the number of revolutions made by the stepper motor for a given profile length.

#### 121 Model for calculating machining time

122 Linear speed is given as the rate of change of distance moved with time, i.e.

123 Speed = 
$$\frac{Distance}{Time}$$
.....(2)

But in the case of HG LCY 300, the cutting speed is given in revolution per minute, (rev/min),i.e.

126 Cutting Speed = 
$$\frac{Number \ of \ revolution}{Time \ (min)}$$
.....(3)

127 Therefore, machining time (T) in second is,

128 
$$T = \frac{Number of revolution X 60}{Cutting Speed}$$
.....(4)

129 Substituting equation (1) for number of revolution in (4), we have,

130

131 
$$T = \frac{Profile \ length \ X \ 60}{Cutting \ Speed \ X \ 0.9973}$$
.....(5)

132 Equation (5) is the model for calculating machining time in seconds for a given profile length.

#### 133 Validation of the model

The model was used to calculate the machining time for profiles 1 to 5 shown in fig. 2. The results obtained were compared to the actual machining time recorded in the process of cutting; these actual cutting/machining times are usually displayed by the computer system. The results are shown in table 2.

153 Figure 5: Graph of prof. 3

155 Figure 6: Graph of prof. 4

157 Figure 7: Graph of prof. 5

Comparing the results in table 2 and figures 3 to 7, it was observed that there is a slight difference, in the order of milli-seconds, between the actual and calculated machining time. This is probably due to the fact that the laser cutting machine is not designed to recognize machining time in decimal values. It actually displays the time in whole number. Therefore, rounding off the calculated machining time to the nearest whole number makes it exactly the same as the actual machining time. Since there is only a slight difference between the actual and calculated machining time, the model is validated.

- 165 **Conclusion and recommendation**
- 166 The objective of the work was achieved, and the model was validated using the five test profiles.
- 167 The slight differences seen between the actual and calculated machining times are attributed to
- 168 the inability of the machine to display decimal values.
- 169 The value of the machine would further be enhanced with this work if properly implemented. As
- a form of recommendation, the CNC 2000 software of the HG LCY 300 should be upgraded by
- 171 adopting this validated model in its program design.
- 172 Furthermore, work is presently on-going on the application of this approach to predicting the
- 173 machining time of CNC lathe and milling machines in the institute.
