### Review Paper

## A Survey of Optimal Power Flow Analysis of Longitudinal Power System

#### ABSTRACT

This paper presented a survey of publications on Optimal Power Flow (OPF) analysis of longitudinal power system with emphasis on the Nigerian power grid. It explained the nitty-gritty of OPF optimal power flow analysis. The study revealed that application of heuristic

optimization techniques to <a>OPF optimal power flow</a> analysis have obviated the drawbacks of the

previously used traditional optimization techniques with better solution quality, convergence time and flexibility. Although, the heuristics techniques were not flawless but well off to that of traditional techniques, a careful hybridization of both techniques werewas seeming best off. This publication will be found handy for power system operators as well as researchers in an attempt to enhance the operations of the electrical power system.

Keywords: Longitudinal power system; Nigerian power system; optimal power flow; power system optimization.

#### 1. INTRODUCTION

Now a Now a days, electrical power is an indispensable product and continues to grow in importance due to its flexibility and other advantages over the other forms of energy. In a deregulated electricity of developing nations, with longitudinal structure of power grid; radial in operation with several long transmission lines where generation centers are sparse and remote from load centers, like the case of Chilean, Nigerian, Taiwan etc. power system. The continuous increase in power demand is fast outpacing the power system infrastructures, which comprises of the generation, transmission and distribution system as well as other ancillary power system equipment; as such, such as, operational violations, complexities and

vagaries become evident on such system.

Technically, construction of a new power infrastructure is not only insufficient as a remedy of combating the menace, but also militated against by problem right-of-way, environmental or socio-political issue, as well as energy resources management [1]. More so, construction of a new power infrastructure is rather a futuristic approach; cannot meet the present energy need. Enhancement or optimum utilization of the existing power system becomes a viable resort. However, the performance indices of the system in terms of security, reliability, stability and economical operation have to be in line with the enhancement. This is the concept of Optimal Power Flow (OPF), the subject of this article.

Optimal Power Flow (OPF) is an optimization process applied to power system, it has been widely used in power system operations, analysis, scheduling, planning and energy

39 40	management over the years and it is still becoming more relevant because of its several capabilities to deal with various situations of modern power system operations [2]. The	
40	capabilities to dear with various situations of modern power system operations (operations)	

optimization process is applicable to power system analysis based on the possibility of modeling power system parameters in terms of variables, constraints and objective function. In power system parlance<sub>2</sub>, OPF is the process of obtaining the optimal setting of the control or decision variables within the electrical power network by optimizing (minimizing or maximizing) objective function of interest without violating the power flow constraints as well as the equipment operating limits while maintaining acceptable system performance in terms of generator capability limits, line flows and output of the compensating devices [3].

Like the conventional (non-optimal) power flow, OPF is also useful for real-time control, operational planning, scheduling, modern Energy Management Systems (EMSs) and also support deregulation transactions of electrical power system. Though the load flow is bereft of yielding the most economic, secured and optimum power system operation but in most cases, it serves as a precursor for OPF. While the economic dispatch, which is a particular case of OPF ignores or sometimes, partly up-keep the security of the system, but the OPF has the capability to determine the holistic optimal power system operation [1]. OPF, also helps in determining the marginal cost data which in turn aids the pricing aspect of power system operation. It also furnishes the dispatchers or power system operators with possible tradeoffs between different objectives and also enlightens on which of the objectives will pay off, without violation of constraints.

A typical OPF problem is formulated in cognizance to the power network model, objective function, operating limits, and the intended solution technique. Due to its versatility, different formulations represent each of the possible cases of OPF and the quality of the result relies on accurate model formulation as well as the solution techniques. Among the OPF formulations are [1],[3],[4]:

- 1. Optimal Scheduling: ensuring optimal generation with a saving (proper allocation) of the energy resources (fuel) invariably a saving in operating cost (fuel cost in thermal plants), such is a case of OPF called; classical economic dispatch [3].
- Security Constrained Optimal Power Flow (SCOPF): Curtailing outages and contingencies while ensuring optimum system operation. Also is the Security Constrained with Voltage Stability (SCOPF-VS) another particular case of OPF [4].
- 3. The scope of OPF can also be extended to accommodate Flexible Alternating Current Transmission System (FACTS) devices as well as renewable energy generation 44.

74<u>75</u> 

76 2. METHODOLOGY

The methodology of OPF is synonymous to that of a typical optimization process, with the appropriate problem formulation in terms of objective function, variables, and constraints such that it captures the desire of the system operators; then, the deployment of solution methodologies or optimization techniques.

#### 2.1 Optimal Power Fflow Fformulation

Several OPF formulations have been reported in the literature to address several instances of the problem. In recent times, the restructuring and developments in power system are causing increment in electric power system complexity. Also, the advent of Independent Power Producers (IPPs) and, the prospect of integrating distributed, and renewable generation in the grid, further expand the scope of OPF. Thus, various formulations abound, which goes by many names depending on choice of objective function and the constraints. Regardless of the name, any power systems optimization problem that includes a set of power flow equations in the constraints may be classified as a form of OPF [5].

172 2.1.3 Objective Ffunction

173 174 175 176 177 178 179 180	Practical OPF problems have several objective functions to reflect the different possible operations of power system. T, the objective function is multi-faceted as no single objective function fit into all the emerging scenarios of OPF. The selection and consideration of the objective functions depend on the operating philosophy of the power system operator [1]. The most commonly used objective function is the minimization of generation costs with and without consideration of system losses, since the issue of cost used to take precedence in power system operations. This is the <a href="elassical_classic">elassical_classic</a> case of OPF, <a href="which is">which is</a> called economic dispatch.  Classical economic Classical economic dispatch controls only the generation units to dispatch while OPF controls all power flow within the electrical power system [3].	
182 183 184 185 186	It is to be noted that the cost, is the operating cost and not the total capital outlay of the power system, which is known in thermal and nuclear stations as the fuel cost. But for the case of hydro plants, where water is seeming free, there exist techniques for hydro scheme coordination as well as for incorporating pumped-storage hydro units into OPF formulation [12]. The fuel cost is usually equated to the operating cost or generating cost with the realization that realization —other that other variables cost like: labour cost, maintenance cost, and fuel	
188 189 190 191	transportation cost, etc which are difficult to express directly as a function of the output of the thermal generator unit, areunit, expressed as a fixed portion of the fuel cost [3],[10].  Emphatically, fixed costs, such as the capital cost of installing equipment, are not included, only those only exests that are a function of unit power output are considered in	
191	the OPF formulation.	
193 194 195 196	Besides minimization of generation costs, other objectives function are the minimization of system losses, maximization of power quality often through minimization from a given given schedule of a control variable (such as voltage deviation) maximization of voltage stability, load curtailment and emissionand of certain gases etc. Sometimes, in a multi-objective problems, the objective functions are augmented with respect to each other, where	Comment [a17]: Here if you use other, then function should be plural. i.e functions. This will make sense. Or you could use another and leave function as singular word, but you need to change are to be is.
198 199 200 201	importance is attached to a particular objective using the method of weighted sum, as seen in [11].	 Comment [a18]: Or presented in ref. [11].
202	2.2 Optimization Techniques	
203 204 205 206	The wide varieties of OPF formulations and the nature of the OPF problems, as previously discussed, brought about wide varieties of optimization techniques. In the past decades, OPF algorithms or techniques were designed in line with simplified assumptions of the problem formulation. Such techniques were termed as traditional or deterministic or better	
207	still mathematical optimization technique. The technique The technique have been applied to OPF	 Comment [a19]: Technique is single word you must use has
208 209 210	problems and were was used in power industry. However, they suffer some shortcomings, mainly as a result of the simplification made in the formulation of the problem, without which the technique might not converge, making the traditional have minimal applications [13].	Comment [a20]: We do not use third party in academic writing. What pronoun "they" mentioned for?
211	However, the However, the new dawn in optimization computations are the heuristics or non	
212 213 214	deterministic optimization techniques, which differ conceptually from the traditional techniques, and are found to outweigh the shortcoming of the previously used traditional methods [methods [13]. It is to however is however noted that, there are still no known universal or almighty	

Comment [a16]: Of what?

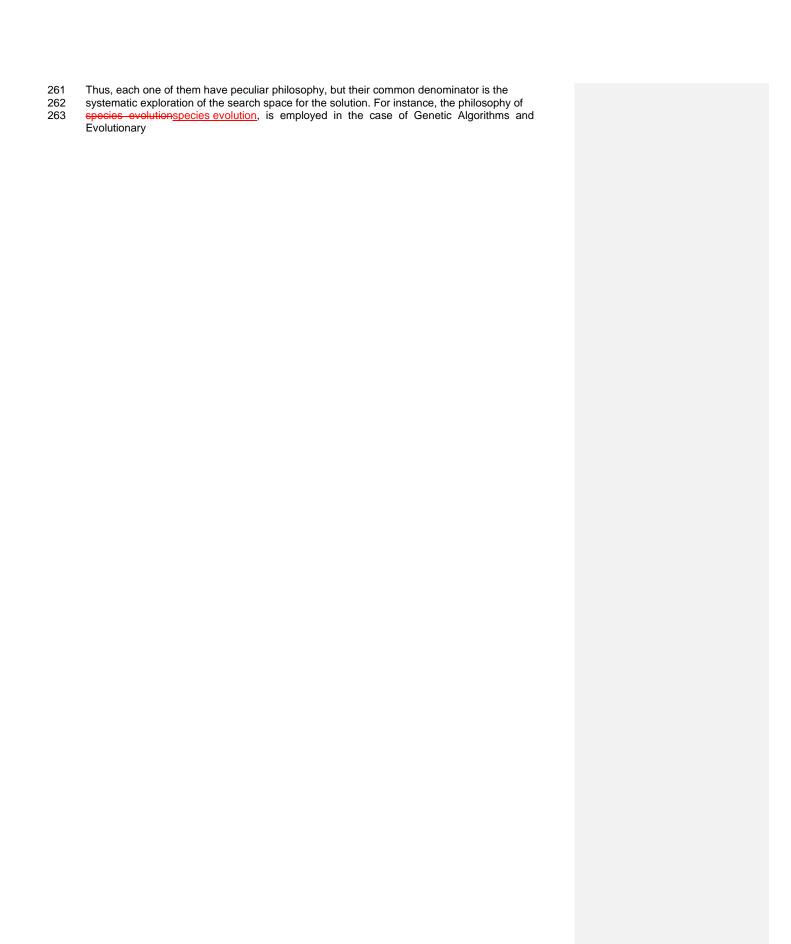

215 216 217 218 219	techniques that fits exactly for all varieties of the OPF problems, although some algorithms might perform excellently well than others in certain OPF model. A common theorem in this aspect of study is the no free lunch theorem; which states, no algorithms in all aspect is better than the other except in certain aspect where one may sutweighsoutweigh the others [14]. The heuristic techniques are, however, reported with many theoretical advantages and practically outperform the classical techniques. Though, they are computational intensive,	

221 222 223 224 225 226	package is burdensome relative to the traditional or deterministic techniques. Some of the performance metrics for discerning between the algorithms as used in OPF researches, were identified by [15] [16] as follows: computational speed, reliability, robustness, versatility or flexibility, scalability, solution quality and time of convergence. Evidently, it is very difficult for a single algorithm to possess all these traits. However, [16] stated that solution quality,
227 228	robustness, time of convergence, reliability, and scalability should be considered in choosing and rating an OPF optimization techniques.
229	2.2.1 Traditional or Deleterministic Oeptimization Techniques
230 231 232	These techniques are principally based on the criterion of local search for the optimal solution through the feasible region of the solution, they use single path search methods and follow deterministic transition rules. Also known as derivative-based optimization methods,
233 234	as its employed gradient and Hessian operators [5]. In these techniques, the criterion for optimality is based on Karush-Kuhn-Tucker (KKT) criterion which is a necessary but not
235	sufficient criterion for optimality. These techniques These have techniques have been widely used in solving
236 237 238	optimization problems and OPF problems in particular, the reason being their efficiency, simplicity, solid mathematical foundation and readily available software tools for their implementation [2].
239 240 241	Common among these techniques as applied to OPF are: Newton method, simplex method, Lambda-iterative techniques, Gradient-based techniques, Linear and non-linear programming, Quadratic programming, Quadratic and dynamic programming and interior point method etc [13]
242	However, in However, in spite of their application to OPF problem, the techniques suffer from the
243 244	following drawbacks which make them to have minimal applications in solving practical OPF problems as reported in [13], [2], [5]-:]:
245 246 247	<ul> <li>Local solvers; cannot guarantee global optimality except for the case of convex problem; because the Karush-Kuhn-Tucker (KKT) conditions are not sufficient for a global optimum.</li> </ul>
248 249	<ul> <li>Uses Uses approximate assumptions (such as linearity, differentiability, convexity etc.) which are unlike practical OPF problem.</li> </ul>
250	<ul> <li>Sensitive Sensitive to objective function and the initial estimate or starting points.</li> </ul>
251 252	<ul> <li>The The majority are meant to handle continuous variables, whereas the practical power system consist of binary or integer and discrete variables.</li> </ul>
253	2.2.2 Heuristic or Non - Deleterministic Oeptimization Techniques
254 255 256 257 258	These techniques employed exhaustive or stochastic search with randomness in moving from one solution to the next in the feasible solution region to obtain the optimal solution. This majorly helps in circumventing being trapped in local minima. Thus, they are versatile in handling various OPF format even with non-convexities and complicating constraints that are typical of practical OPF practical OPF. These techniques are evolved to overcome the drawbacks of
259	conventional techniques .Mosttechniques. Most of these techniques imitate certain natural phenomenon in
260	their search for an optimal solution, which brought about their various categories [17].

#### 3. PREVIOUS STUDIES

Application of the variants of Genetic Algorithm (GA) to the problem of economic dispatch of generation was the focus of [27]. In this study, both the Conventional Genetic Algorithm (CGA) and Micro Genetic Algorithm ( $\mu$ GA) were applied to minimize the generation cost, the power balance constraints was the equality constraints considered. The authors reported that the major drawback of the conventional genetic algorithms approach was that it can be time consuming. Micro genetic algorithms approach was proposed as a better time efficient alternative. The effectiveness of both techniques to solving economic dispatch problem was initially verified on a 6-bus IEEE test system and then on the 31-bus Nigerian grid systems. It was concluded that the results obtained from both approaches were satisfactory. However, from the view point of economic and computational time, micro genetic algorithms performed better than the conventional genetic algorithms and overly better to that of Newton-approach, on both the 6-bus IEEE test system and then on the 31-bus longitudinal Nigerian grid systems.

In [28], voltage profile correction and power loss minimization through reactive power control using Differential Evolution (DE) and Particle Swarm Optimization (PSO) technique was investigated. The feasibility, effectiveness and generic nature of both Differential Evolution (DE) and Particle Swarm Optimization (PSO) approaches were demonstrated on the 31- bus Nigerian grid system and the 39- bus New England power system with MATLAB application package. The simulation results revealed that both approaches were able to remove the voltage limit violations, but Particle Swarm Optimization (PSO) procured in some instances slightly higher power loss reduction as compared with Differential Evolution (DE). However, Differential Evolution (DE) was observed to require a considerably lower number of function evaluations while compared with Particle Swarm Optimization (PSO), if this observation could be substantiated by further investigation on the longitudinal Nigerian grid system, the DE approach will be more viable for potential real time application in control centre where the computation time is very relevant.

More so, the Elitist Non-dominated Sorting Genetic Algorithm II (NSGA-II), was applied to solve the multi-objective optimal dispatch of the Nigerian 24-bus hydrothermal power system with fuel cost and transmission loss as the objectives, with the consideration of power balance [29]. The authors established that the solutions obtained by elitist non-dominated sorting genetic algorithm (NSGA-II) converged better over both conventional genetic algorithms and micro genetic algorithms approaches used in earlier studies on the Nigerian power grid. It was observed that as the modification of the algorithm increases, their performance get better.

The optimal dispatch of generation with the minimization of system total generation cost, subjected to power balance constraint equation using Newton Raphson iterative techniques was examined in [30]. This iterative techniques was applied to Nigerian grid system to determine the total cost of generation as well as the total system transmission losses. While the simulation was done with a MATLAB based program. At certain buses where voltage drops were noticed, Load Tap-changing Transformer (LTCT) were introduced to adjust the voltage magnitude, which furthered reduced the losses on the system. It was observed that the optimality in this study was determined based on Karush-Kuhn-Tucker (KKT) criterion; being a traditional technique, the result obtained trailed that of previous works ([27],[28]and [28]) in solution quality.

Constrained Elitist Genetic Algorithm (CEGA) was adopted in [31] to solve the economic

**Comment [a25]:** I would be recommended to add finding result as section her

Also, this section need to be include in introduction section

load dispatch problem of the 31-bus Nigerian power system, to reduce both the transmission power loss and total cost of generation, while maintaining an acceptable generation output. Simulation results show that CEGA performed better while comparing with the result of the micro genetic algorithm (µGA) and a Conventional Genetic Algorithm (CGA), previously used with the same data set as reported in [27]. It was observed that the modification of the algorithm brought about a better result for the Nigerian power grid.

The optimal load dispatch in the South / South Zone of Nigeria Power System by means of a Particle Swarm optimization and Lambda-iteration techniques was investigated in [32]. The economic load dispatch problem were solved for two different cases, the Sapele plant with three units in generating stations and the Afam plant, with six units in the generating stations. The analysis was simulated on MATLAB software package. The objective was cost minimization with and without consideration of losses. It was reported that PSO gave a better solution in terms fuel cost and losses when compared to the result obtained by lambda-iteration, for the same test case.

372<u>373</u> 

#### 4. CONCLUSION

This paper has dissected and presented the nitty-gritty of OPF analysis of a longitudinal power grid with emphasis on the Nigerian power system. From the reviewed works, the heuristic or non – deterministic optimization techniques demonstrated its effectiveness and superiority over the traditional techniques with a better numerical result and computational time unlike the traditional techniques. Although, the programming aspect or the development of software package of the heuristics techniques might be tedious relative to traditional techniques. Noteworthy also, the performance of the non-deterministic techniques get better as their modification and hybridization increases. These are eue forcue for further works. Subsequent works should leverage on the application of non – deterministic and combinatorial (hybrid) optimization techniques to solving OPF problems.

More so, it was evident from the review that bulk of the studies focused on generation cost and transmission losses minimization; a particular case of OPF called economic dispatch. Extension of the scope of OPF to accommodate other operational constraints and objectives with the consideration of FACTS controllers, hydro-plants and to distributed generations, are also recommended; if included in the analysis, this will further enhance the performance and operation of the power system.
