

DIAGNOSING THE DIMENSIONS OF BENEFITS AND CONSTRAINTS OF ICT UTILIZATION AMONG CASSAVA FARMERS IN UYO AGRICULTURAL ZONE, SOUTH-SOUTH NIGERIA.

ABSTRACT

Major dimensions of benefits and constraints of ICTs utilization among cassava farmers in Uyo agricultural zone were assessed in this study. A multi-stage sampling method was used to select 100 respondents for the study. The study relied on primary data gathered through the use of well designed and validated questionnaire. Factor analysis technique and composite index were adopted to ascertain the major dimensions of benefits and constraints of ICTs utilization among cassava farmers as well as the level of severity of the constraints that are responsible for the sub-optimal cassava production in Uyo agricultural zone. The major dimensions of benefits of ICTs utilization perceived by the respondents in the study area include; promotion of access to cassava production, processing and marketing information; promotion of easy access and sharing of information on improved cassava varieties, weather forecasting and credit facilities for cassava production; Promotion of adoption of cassava production innovations and Promotion of effective cassava production leading to rural development. Findings also revealed that the numerous constraints to the use of ICT tools by cassava farmers in Uyo agricultural zone unlocked separately into government policies, technological and administrative constraints as the major dimensions of constraints. How rewarding the efforts on improvement of cassava would be, even in the nearest future, would depend to a large extent on the elimination of these major constraints. Unless pragmatic approach is used to reduce the constraints responsible for the low utilization rate of ICTs, food security in Uyo agricultural zone, South-south, Nigeria, would still be elusive.

Keywords: Diagnostics, dimensions, Constraints, Benefits, ICTs, Utilization, Cassava farmers

Introduction

Undoubtedly, application of ICTs to agriculture may be a relatively new phenomenon in developing countries, but ICT's contributions to agricultural development and poverty alleviation is becoming increasingly noticeable. ICT's contribution to food security and rural livelihoods has gained increased recognition and was endorsed officially at the World Summit on the Information Society in 2005 (International Institute for Communication and Development (IICD, 2007). According to IICD (2007), increase in efficiency, productivity and sustainability of small scale farms have been observed in areas where ICTs' utilization for agricultural production have been significant. ICTs can be defined as those technologies used in collecting, processing, storing, retrieving, disseminating and implementing data and information using microelectronics, optics, telecommunication and computers (FAO, 1993).

Comment [001]: Give the meaning of this acronym in this title and let it (ICT) be in bracket.

Comment [002]: You can be using this acronym freely only when the meaning is given. Give the meaning of this acronym ICT first.

Comment [003]: You may reduce your keywords to maximum of 5.

Comment [004]: You can be using this acronym freely only when the meaning is given. Give the meaning of this acronym ICT first.

They are also defined as those technologies that facilitate communication, processing and transmission of information by electronic means for the benefits of its users (Technical Centre for Agricultural and Rural Cooperation (CTA), 2003).

The definition above implies that the use of ICTs in cassava production and extension services would be quite essential for rural development, especially now that its use has witnessed an upsurge in almost all areas of rural life in several African countries, (CTA, 2003). Cassava (*manihot spp*) is one of the most popular root crops grown in West Africa especially in Nigeria (Nsoanya and Nenna, 2011). The Federal Government of Nigeria has, in recent times, placed much emphasis on cassava production in all the states of the country because of the variety of uses the crop could be put to, (Nsoanya and Nenna, 2011). Therefore, stakeholders in cassava production can access information and knowledge about the crop through ICTs. ICTs can also improve market access through the awareness of up-to-date market information on cassava production prices, inputs and consumers needs. This can improve cassava farmers' livelihood substantially and has a dramatic impact on their negative position.

Furthermore, ICTs according to Agada and Akpan (2017) enable cassava farmers in the rural communities to interact with other stakeholders, thus reducing social isolation. ICTs widen the perspective of rural communities in terms of national and global development, open up new business opportunities and allow easier contact with friends and relatives as well as help eliminate the gap between agricultural knowledge and rural communities. As observed by UNESCO (2002), many countries of the world now regard understanding ICT and mastering its basic skills and concepts as part of the core of education alongside, reading, writing and numeracy. ICTs used by cassava farmers according to Odame, Hafkin, Weseler & Boto (2002) and Arokoyo (2005) include radio, television, fixed and mobile phones, short message services (SMS), world wide web (www), search engines, packet digital assistants, cameras, video, e-mail, computer, contact data bases and systems, CD-Rom, DVD, rural radio and web publishing, among others. These ICT tools were also rated as highly relevance to cassava production activities in the areas of cassava stem selection, land preparation, marketing of produce, land selection for cassava, sowing/planting of cassava, fertilizer application and transportation, (Olaniyi, Adetumbi, and Adereti (2013). In another dimension of benefits, Simonyan, and Joshua, (2014) observed that ICTs can provide cassava farmers with information on improved cassava varieties, weather forecasting, pest control and other agricultural related services. More so, ICTs can deliver timely information to farmers which can help boost their productivity and income (Simonyan, and Joshua, 2014). Agada and

Comment [005]: Use and instead of the sign "&".

Comment [006]: Capitalize each words.

Comment [007]: Capitalize each words.

Akpan (2017) reported that cassava farming has been upgraded from being just a staple food to a source of income as well. Cassava farmers therefore, must access and use ICTs to optimize production in order to meet the increasing demand both locally and internationally.

Affirmatively, ICTs holds a lot of benefits for cassava farmers but the effectiveness and efficacy of cassava farmers in Uyo agricultural zone, south-south Nigeria to key in and enjoy these benefits as well as achieve sustainable production depends upon the extent to which they are free from constraints towards the utilization of these ICTs. Despite the fact that there are a number of factors encouraging farmers to utilize ICTs, literatures have identified a wide range of barriers and constraints to ICTs utilization, some of which are true for farming in general and some of which are particular to cassava farming. Arokoyo, (2011) reported that rural farmers in Nigeria, including cassava farmers have not been able to substantially adopt ICTs to increase productivity. Reasons advanced for this scenario include low level of ICT readiness, poor ICT infrastructure, erratic and unstable power supply, limited and high cost of telephone services, limited access to computers and internet, lack of communication policy by government, high level of rural poverty, high level of illiteracy, policy inconsistency and commercialization of radio stations, among others.

Some years later, Obinna, (2014) in his study on information and communication technologies used by female cassava farmers in Umuahia agricultural zone, Abia State, observed that cassava farmers could not use most of the computer based ICT components due to their high computer illiteracy coupled with other barriers and stressed on the need to build the capacity of the women farmers in computer skills and literacy and to encourage them to own personal computers, to benefit fully from the advantages offered by the ICT technologies in modern agriculture. A more recent study carried out by Agada and Akpan (2017) reported that constraints to access and use of ICTs by cassava farmers in Obudu, Cross River State were low income earning, poor access to ICT training, poor access to ICT infrastructure and lack of time among others.

Unarguably, some studies have been done on ICTs utilization by cassava farmers but studies that have examined the dimensions and severity of constraints faced by cassava farmers in utilizing ICTs were scarce in Uyo agricultural zone, South-south Nigeria. There is need to further expand the frontier of knowledge and learning, by making available empirical information on the dimensions and severity of constraints faced by cassava farmers in utilizing ICTs as well as the dimensions of perceived benefits of ICTs' utilization among the farmers. Therefore, this study was set to fill this gap by focusing on dimensions of perceived

Comment [008]: Capitalize each words.

Comment [009]: Capitalize each words.

benefits of ICTs' utilization as well as the dimensions and severity of constraints faced by cassava farmers in utilizing ICTs in Uyo agricultural zone of Akwa Ibom State.

Specifically, the study;

1. diagnosed the major dimensions of perceived benefits of ICTs utilization among the cassava farmers in the study area
2. examined the levels of benefits of ICTs among the cassava farmers.
3. diagnosed the major dimensions of constraints to ICTs utilization among the cassava farmers in the study area.
4. examined the level of severity of the constraints to ICTs utilization among the cassava farmers in the study area.

Methodology

The study was carried out in the Uyo Agricultural Zone in the South-south region of Nigeria. Uyo Agricultural Zone is made up of Ibesikpo, Uyo, Uruan, Itu and Ibiono Local Government Areas. The area falls under the rainforest zone with mean annual rainfall of about 2484mm, annual temperature is about 27°C and relative humidity ranges from 70 – 80 percent (Ebong and Enyenihi, 2015). Two distinct seasons are discernible; the dry season (November – March) and rainy season (April – October). The study area is centrally located in Akwa Ibom state, and as the commercial nerve centre assumes extra importance in the state. Economic activities of the inhabitants are farming, trading, crafts, transportation, civil service, artisans etc. The area has a large concentration of cassava farms and numerous cassava processing mills (Ebong and Enyenihi, 2015).

The selection of respondents was based on the Akwa Ibom State Agricultural Development Programme (AKADEP) framework. A multi-stage sampling method was used to select the respondents. First, the Uyo zone was purposively selected for the study. The second stage involved a simple random sampling (by ballot) of 5 out of 8 blocks from the zone while the third and fourth stages deployed the use of simple random sampling for the selection of 5 cells from the selected block and 20 cassava farmers from each cell. A total of 100 cassava farmers were selected for the study.

This study relied on primary data gathered through the use of well designed and validated questionnaire. The questionnaire was administered on the selected respondents in the study area. Descriptive and inferential statistical tools were used for data analysis. Descriptive statistical tools included frequency counts, percentages, mean as well as composite index while inferential statistical tool used included Factor analytical procedures.

Comment [OO10]: This study objectives may not necessarily be itemized by numbering it. Let the objectives be written in flowing sentences with each objective separated by a comma until the last objective.

Results

Naming of the Major Dimensions of Perceived Benefits of ICT Utilization among the Cassava Farmers in the Study Area

Twenty-four items were initially generated and validated during the instrument construction phase to reflect this objective. Factor analytic procedure primarily analysed the interrelationship among variables (scale items) in terms of their underlying dimensions (factors). Factor analysis using principal component approach was used to produce linear combinations of these items or variables and a small number of these combinations typically account for the majority of the variability within the set of intercorrelations among the original variables. Its goal is to extract the maximum variance from a data set, resulting in a few orthogonal (uncorrelated) components.

The first principal component is the combination that accounts for the largest amount of variance in the sample. The second principal component accounts for the next largest amount of variance in the sample and is uncorrelated with the first. The researcher used the Kaiser's rule criterion to decide the number of components to retain and interpret. The rule states that only those components of an instrument that account for variances greater than 1 (i.e eigen value greater than 1) should be retained (Kaiser and Caffry, 1965). The researcher however examined the communality values when determining the selection of eigen value for extraction of factors. Communalities extraction expresses the amount of variance accounted for by the number of factors extracted in a variable matrix, taken together. Thus, the size of the communality extraction value therefore assesses how much variance in a particular variable is accounted for by the others in the factor solution. The index of communality extraction tells the degree which a particular variable or item relates with other variable included in the analysis, and vice-versa.

The 4 components with their corresponding items (statements) shown in Table 1 were merged whenever they were judged to be conceptually related. This is consistent with recommendations by Spector (1992), Churchill (1995) and Hair et al (1998), who stated that the deletion or merger of a particular statement/item can only be justified when the item (s) to be eliminated or merged are conceptually related with another group items. This resulted in the generation of 4 major dimensions of perceived benefits of ICT utilization among the cassava farmers in the study area, which is in consonance with the 4 underlying components of the 24 valid items earlier generated. Component one accounted for 48.705% of the variance in the data, this was followed by component two with 12.269% variance, followed

Comment [OO11]: This should be results and discussion section and not only results.

by component three with 9.550%, and then component four which accounted for 4.693% of the variance. The components are named as:

Component 1: This component containing nine (9) items which loaded positively in excess of 0.5 is appropriately tagged **promotion of access to cassava production, processing and marketing information**. This is because most of the items are concerned with the respondents feeling satisfied with ICTs for allowing them access to cassava production processing and marketing information. This finding indicates that, ICT is very relevance to cassava production activities especially for both pre planting and post planting operations. The fact that, ICT is relevant to marketing of cassava produce is in line with the findings of Usman et al. (2012) that, marketing information is one of the most relevant ICTs services which could be offered to farmers in Nigeria.

Component 2: This factor containing six (6) items which loaded positively in excess of 0.5 is appropriately tagged **promotion of easy access and sharing of information on improved cassava varieties, weather forecasting and credit facilities for cassava production**. This is because most of the items are concerned with the respondents feeling satisfied with ICTs for giving them access to information and enabling the sharing of information on improved cassava varieties, weather forecasting and credit facilities for cassava production among themselves. This findings agrees with Simonyan, and Joshua, (2014) who posited that ICTs can provide cassava farmers with information on improved cassava varieties, weather forecasting, pest control and other agricultural related services. More so, ICTs can deliver timely information to farmers which can help boost their productivity and income (Simonyan, and Joshua, 2014).

Component 3: This factor containing five items which loaded positively in excess of 0.5 is appropriately tagged **Promotion of adoption of cassava production innovations**. This is because the items gave insight into the usage of ICTs that led the respondents to search for and decided to adopt cassava production innovations.

Component 4: This factor containing four items which loaded positively in excess of 0.5 is appropriately tagged **Promotion of effective cassava production leading to rural development**. This is because the respondents believed that the use of ICTs has enabled them to produce effectively with resultant improvement on yield and income. These improvements of course will contribute positively to economic growth and development of the study area. ICTs according to Agada and Akpan (2017) enabled cassava farmers in the rural communities to interact with other stakeholders, thus reducing social isolation. ICTs widen the perspective of rural communities in terms of national and global development, open up

211 new business opportunities and allow easier contact with friends and relatives as well as help
212 eliminate the gap between agricultural knowledge and rural communities.

219 **Level of Perceived Benefits of ICTs among the Cassava Farmers (LBICTCF)**

220 The level of perceived benefit of ICTs among the cassava farmers was estimated using
 221 composite index approach. The index range lies within 0.00 and 1.00, as the respondents
 222 estimated index tends towards 1.00, it implies that their level of benefit was extremely high
 223 and vice versa as it tends towards 0.00. However, for ease of analysis, the index of each item
 224 was distributed along a categorized level of perceived benefit based on equal interval, such
 225 that 0.00 – 0.500 indicates low level of benefit, 0.5001 – 0.750 indicates average level of
 226 benefit while 0.7501 – 1.00 indicates high level of benefit of ICTs. Result of the analysis as
 227 shown on table 2 revealed that majority (76.0%) of the respondents perceived high level of
 228 benefit from utilization of ICTs; 20.0% perceived average level of benefit while only 4.0%
 229 perceived low of benefit from the use of ICTs. This depicts that a good number of the cassava
 230 farmers perceived that the use of ICTs can be highly beneficial.

234

235

236 **Naming of the Major Dimensions of Constraints to ICTs Utilization among the**
 237 **Cassava Farmers in the Study Area**

238 Factor analysis was used to establish the underlying interrelations existing among the
 239 very many variables identified as constraints to the use of ICT tools by the cassava farmers.
 240 This makes it possible to reduce the variables to a more meaningful framework. In the
 241 preliminary analysis, the Kaiser-Meyer-Olkin (KMO) test of sampling adequacy achieved a
 242 score of 0.821. All the 19 factors had communalities of 1.00 or higher, indicating their
 243 appropriateness for the factor analysis. The 19 significant factors were further reduced to
 244 common factor patterns. This was done to empirically explain the constraints to the use of
 245 ICT tools by the cassava farmers. In doing this, principal component analysis with Varimax
 246 rotation and Kaizer Normalisation was used to determine which factors have significance.
 247 Factor retention was based on eigenvalue of 1.0. Only factors hat account for variances
 248 greater than 1.0 were included in the factor extraction.

249 Three (3) underlying themes or components were obtained using a cut-off point of
250 0.50.

251 **For component 1;** Lack of government policies to enhance the development of ICT in
252 rural areas highest with a factor loading of 0.853, followed by High cost of
253 Telecommunication service (0.802), Low ICT literacy level (0.802), High cost of
254 maintenance of ICT (0.792), Inadequate access to ICT (0.749) and Complexity in using ICTs
255 (0.725) in that order.

256 **For component 2;** Low Technical knowhow emerged highest with a loading of 0.852,
257 followed by High cost of ICT tools (0.835), Lack of adequate awareness of ICT (0.821) and
258 Poor electricity Service (0.812).

259 **For component 3;** Lack of internet services in rural areas emerged highest (0.797), followed
260 by High cost of repairing ICTs (0.718), Negative attitude of people towards change (0.694),
261 Lack of Finance to acquire ICT tools (0.678), and Household commitment and hindrances
262 (0.602).

263 Given that most of the variables in component 1 are directly or indirectly linked to
264 issues relating to government policies and the component was therefore labeled as
265 government policies and related constraints. Similarly, given that most of the variables in
266 component 2 are linked to technology know how issues, this has been labeled as
267 technological and related constraints. Then component 3, was named administrative
268 constraints. To this effect, the numerous constraints to the use of ICT tools by cassava in Uyo
269 agricultural zone unlock separately unto issues relating to government policies and related
270 constraints, technological and related constraints, and administrative constraints.

271 **Table 3: Principal Components Analysis for Major Dimensions of Constraints to ICTs Utilization among**
272 **the Cassava Farmers in the Study Area.**

276 **Level of Severity of the Constraints to ICTs Utilization among the Cassava**
277 **Farmers in the Study Area**

278 The level of severity of constraints to utilization of ICTs among the cassava farmers
279 was estimated using composite index approach. The index range lies within 0.00 and 1.00, as
280 the respondents estimated index tends towards 1.00, it implies that severity of constraints was
281 extremely high and vice versa as it tends towards 0.00. However, for ease of analysis, the
282 index of each item was distributed along a categorized level of perceived constraints based on
283 equal interval, such that 0.00 – 0.500 indicates low severity of constraints, 0.5001 – 0.750
284 indicates average level of constraints while 0.7501 – 1.00 indicates high level of constraints
285 to ICTs utilization. Result of the analysis as shown on table 4 below revealed that 29.0% of
286 the respondents perceived the constraints to be highly severe, majority (61.0%) of the
287 respondents perceived that the constraints were averagely severe while only 10.0% perceived
288 the constraints to the use of ICTs were lowly severe. This finding agrees with Arokoyo,
289 (2011) who reported that rural farmers in Nigeria, including cassava farmers have not been
290 able to substantially adopt ICTs to increase productivity. Reasons advanced for this scenario
291 include; low level of ICT readiness, poor ICT infrastructure, erratic and unstable power
292 supply, limited and high cost of telephone services, limited access to computers and internet,
293 lack of communication policy by government, high level of rural poverty, high level of
294 illiteracy, policy inconsistency and commercialization of radio stations, among others.

Conclusion and Recommendation

The study has revealed that the major dimensions of benefits perceived by the respondents in the study area include; promotion of access to cassava production, processing and marketing information, promotion of easy access and sharing of information on improved cassava varieties, weather forecasting and credit facilities for cassava production, Promotion of adoption of cassava production innovations and Promotion of effective cassava production leading to rural development. The result revealed that a good number of the cassava farmers perceived a high level of benefit from the use of ICTs. On the other hand, the result revealed that the numerous constraints to the use of ICT tools by cassava farmers in Uyo agricultural zone unlock separately into issues relating to government policies and related constraints, technological and related constraints, and administrative constraints as the major dimensions of constraints. However, the study revealed majority (61.0%) of the respondents as perceiving that the constraints were averagely severe.

Given the fact that the Akwa Ibom State Government is currently promoting and empowering cassava farmers which involves women and youth through skill acquisition and production inputs, the study therefore recommends that ICT literacy training be incorporated into the programme and also the number of skill acquisition centers be increased in order to enable more farmers mostly in the study area to benefit. Akwa Ibom State Government should ensure that adequate ICT infrastructure are put in place in the state as to give everyone opportunity to benefit from the use of ICT, since it is the in-thing in this 21st century.
