<sup>1</sup>Department of Environmental and Natural Resources Management, Presbyterian University College Ghana, Akropong-Akuapem, Ghana <sup>2</sup>Korle Bu Teaching Hospital, Korle Bu, Accra, Ghana

**ABSTRACT** 

14 15

The main aim of this study was to investigate the characterizing features of off-season water supplies in the Kwahu-Abetifi Township situated in the Kwahu-East District of Ghana.

A descriptive cross sectional survey was employed for the research.

The study was conducted in the Kwahu East district of Ghana between August 2017 and December 2017.

The stratified sampling technique was employed to select 200 respondents for the study. Respondents were interviewed using prepared and validated questionnaires. Data obtained from the completed questionnaires, were analyzed using the statistical Package for the Social Sciences (SPSS).

The community people including school-going children in the study area, trek long distances and stay in long queues to access water. They however spend long hours in accessing water for use in their homes during the dry season. Durations respondents used in accessing water and returning to their homes were as follows: Approximately 15 minutes (10%, n=200); 20 minutes (16%, n=200); 35 minutes (22%, n=200); and more than 40 minutes (52%, n=200). Nevertheless, the accessed water were perceived to be good (68%, n=200) and were used for several domestic purposes including drinking (19%, n=200), cooking (47%, n=200), bathing and washing (34%, n=200). The study underscored the need for the revamp of broken down water supply systems in the study area and expansion of existing ones by Government to ease and improve accessibility to adequate and potable water supplies mostly during the dry season.

16

Keywords: Potable water supply, off-season, accessibility, proximity, affordability

19

## 20 1. INTRODUCTION

21

22 Ensuring the provision of adequate and potable water supplies to communities across all facets of life 23 around the world is very critical. Good health, livelihood enhancement, sustainable development 24 among other key aspects of life all hinge on the supply of clean and sufficient quantities of water that 25 can be reliable at all times [1,2]. Worldwide, it is estimated that, the total cost of water insecurity 26 affecting the global economy is US\$500 billion [3]. Over the years, there have been incessant 27 concerns at the international, regional, sub-regional and grass root levels concerning issues of potable water supplies to people. Aside the concerns, water supplies in most parts of the world face 28 29 challenges including but not limited to scarcity. It therefore becomes very prudent to address water 30 related issues in the context of scarcity and security, sanitation and health crisis with infrastructure deterioration and destruction to reverse the threatening supply and quality trends. 31

Despite the enormous efforts to improve the supply of potable water to people worldwide, 663 million people suffer inaccessibility to 'improved' drinking water sources [4]. Moreover, the 'improved' water is perceived by many as either not safe, unreliable or not affordable. In respect of water safety, levels of arsenic above World Health Organization (WHO) standards in drinking water consumed by 45 million people in Bangladesh have been documented [5].

In Ghana, scarcity situations have not been different as some communities continue to suffer stern
water shortages usually during the lean season. Several community water connectivity exist, but
equally an appreciable number of communities continue to receive their share of supply challenges,
perhaps as a result of frequent system break down and other factors.

### 41 **1.1 Objectives of the study**

### 42 The main objectives of the study were:

43 To determine the challenges that face water supply accessibility in Abetifi-Kwahu in the Eastern 44 region of Ghana during the dry season.

45 To ascertain the perceived quality of water supplied in Abetifi-Kwahu in the Eastern region of Ghana 46 during the dry season.

47

### 48 **2. The global water cycle and situation**

49 Water, being an important element of life, cycles between land, the oceans and the atmosphere 50 through solid, liquid and gaseous phases. Precipitation from the atmosphere gets to land, 51 underground aquifers and oceans. Rivers get their supplies from groundwater as water moves 52 through sediments and rocks. Rivers intend provide freshwater discharge into seas. Water finally 53 evaporates or transpires from the ocean and land into the atmosphere to complete the cycle.

Earth's water resources including rivers, lakes, oceans and underground aquifers are under stress in many regions worldwide. Of the 70% portion of the Earth's water cover, only 2.5% is freshwater. This limited resource is to support an estimated 9.7 billion of the world's population by 2050 [6]. In sub-Saharan Africa, high population growth triggers high consumption rate of this limited resource. Worldwide, some regions are endowed with freshwater than others as a result of global circulation patterns which translate to distinct wet and dry phases of multi-annual climate cycles.

60 Despite the fact that developed countries have more water available than most of the countries in 61 Africa, Asia and the Pacific, some areas are water-stressed because the available water sources are 62 being depleted at very high rates [7]. It is envisaged that, global water demand would increase by 50% by the year 2030 [8]. Water supply situation, moreover is estimated to be worsened with an 63 64 approximately 3.9 billion (over 40%) of the world's population, to dwell in severely water-stressed 65 basins [6]. Vicinities with water-stressed situations, consequently makes people seek water from very 66 distant sources. With water scarcity affecting over 40% of the world's population, there is the need for 67 urgent interventions and implementation of highly workable strategies [9].

The United Nations and the international community however, set targets to reduce the number of persons with inadequate potable water and sanitation by 2015. Meeting this target was to provide an extra 260,000 people per day with clean drinking water and 370,000 people per day with improved sanitation through the year 2014 due to the escalating global water demand [10].

### 72 **2.1 Community water supplies in Ghana**

In most rural communities of Ghana, people rely on all sorts of water sources during the wet season including streams, rivers, dug wells, ponds, boreholes, rainfall, etc but face the challenge of dryness or severe drought getting to the end of the year. Most commonly, people who dwell in these areas resort to these available water sources, which might not be potable but use them unknowingly at the highest health risk [11]. Provision of clean water, is thus imperative in ensuring that people do not suffer likely detrimental diseases and other health risks. Again, personal hygiene is very essential, and must not receive less attention because of water inaccessibility [8]. Per capita water consumption is reliance on accessibility, which could primarily be defined by distance, time, reliability and cost [12]. There is a higher health benefit when water is rather at the household level. Interventions by Governments, International organizations, and Non-Governmental Organizations have made it possible for several rural communities in Ghana to boast of pipe-borne water for which their accessibility, reliability, permanence, and cost effectiveness are also matters of concern.

Potable water accessibility challenges limit personal and household hygiene, which intend affect public health. A supply system that would ensure the everlasting needs of people and also accessible to all without denying the living poor and the healthy living is key for the development of human lives. There is the utmost need for an affordable and efficient rural water supply system that is sustainable and hinges on an effective logical management framework [13].

91 Sustainable water management is very fundamental in realizing most of the sustainable development 92 goals most especially Sustainable Development Goal (SDG) 6. Thus ensuring the sustainability of 93 rural water supplies through effective management systems is worth considering. This will make 94 people and their immediate environments continue to obtain the right quantities of potable water for 95 growth and development. In most instances, rural water systems unreliability occur due to system 96 breakdown, financial constraints, lack of sense of responsibility for service payment leading to 97 systems failure, poor or no system evaluation and the failure in implementing evaluation 98 recommendations. These factors limit the efficient performance of rural water supply systems. 99

### 100 3.1 DESCRIPTION OF STUDY AREA

101 The study area, Abetifi-Kwahu is located in the Kwahu-East District of the Eastern Region of Ghana. It 102 is geographically located on (6° 40' 0" N, 0° 45' 0" W). The over 15,000 populace of the study area 103 are engaged in several economic activities including farming, trading and public service work. Abetifi-104 Kwahu as the name goes has been and still known for its severe perennial dry season water crises 105 making life difficult for its inhabitants during this portion of the year.

106 The town used to be connected to the water lines of the Kotoso water treatment station making it 107 easier for people who lived mostly in bungalows accessed water in their homes at the time. For the 108 past two decades, the supply lines connected to this water station are damaged and have not been 109 fixed, making the people access quantities of water that are described as scarce and frustrating to 110 find during the dry season. Towns like Nkwatia and Mpraeso are connected to the Ghana Water 111 Company Limited lines but Abetifi has not yet seen its share of this connectivity. During the dry 112 season, rivers, streams as shown in Figure 1 below dry up leaving only the few constructed bore 113 holes with standing pipes and dug wells for the use of the over 15,000 inhabitants of the community.

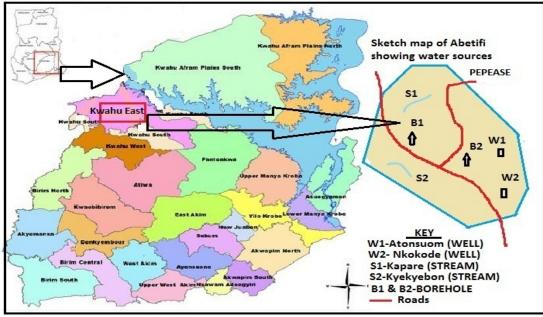

Fig.1. Sketch map of study area showing water sources

### 116 **3.1.1 Climate and rainfall**

117 Lying within the semi-equatorial region, Abetifi is characterized with two rainy seasons in a year, the 118 major and minor rainy seasons. The major rainy season starts from April and ends in July whilst the 119 minor starts from September and ends in October. Annual rainfall averages between 1580mm and 1780mm. The town experiences warmth and dryness between November and March as it is hit by the 120 121 Tropical Continental (cT) air mass [14]. Within the month of February, the highest form of dryness with 122 23mm of rainfall is experienced. Known as the highest inhabited point in Ghana, the town is located 123 about 2080ft above sea level and prides itself with a very serene weather condition with monthly temperature averaging 30°C in the dry season which falls to 26°C during the wet season. Relative 124 125 humidity ranges from 75% to 80%.

### 126 3.1.2 Vegetation

127 The town lies within the Semi-Deciduous forest zone of Ghana [14]. The vegetation is characterized 128 by a dense tree cover with trees shedding off their leaves mostly during the dry season. There exist 129 the lower, middle and upper layers in terms of the tree coverage in the forest. Specifically, these 130 layers include the canopy, understory layer, shrub layer, herbaceous layer and the forest floor. The 131 canopy, the uppermost layer of the vegetation, consists of the upper leaves and branches of the 132 tallest trees. Beneath the canopy, the understory layer consists of small, shorter trees. Beneath the 133 understory layer is the shrub layer consisting of woody vegetation tending to be less than 10 feet high. 134 The herbaceous layer is found beneath the shrub layer and consists of small, soft-stemmed plants such as wildflowers and ferns, as well as grasses. The forest floor, the lowest layer of this forest 135 136 vegetation, consists of fallen leaves, twigs, and branches, as well as small plants such as mosses and 137 lichens.

138 The forest vegetation is rich with several flora most of which, are of immense commercial and 139 scientific values. Trees of economic importance which can be identified in the area include Odum, 140 Wawa, Mahogany, etc [14]. Moreover, trees of commercial and scientific values, which abound in the 141 forest, include Onyina, Emire, Ofram, Bompaghya, Kyenkyen, etc. Until a few centuries ago, the 142 impact of human populations on both the vegetation and cohabiting species was minimal because of 143 small population. In recent times, destruction of this vegetation in the study area caused by human population and economic pressures is considered a major threat to the natural environment. The 144 145 natural vegetation cover continues to deteriorate as a result of activities including farming, logging of 146 wood for timber, indiscriminate bush fires mostly during the dry season. Such activities change the 147 natural vegetation which in tend affect the dynamics of biodiversity in the area.

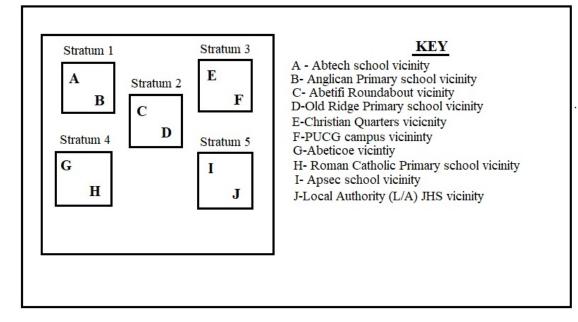

### 148 **3.1.3 Soil**

149 Described as deeply weathered soils, forest ochrosols as the name goes are the type of soils found in 150 the study area [14]. They consist of thin (about 20cm), dark greyish brown, humus-stained, sandy 151 loam and silt loam topsoil which are usually moderate fine granular in structure and friable in 152 consistency. The subsoil are thick, often more than 120cm thick over the weathered substratum. The 153 texture of the subsoil varies and may be sandy clay loam, silty clay loam, sandy clay or silty clay with 154 common to many (10-40%) quartz gravels and stones and hard iron and manganese dioxide 155 concretions [15]. The forest ochrosols are generally slightly to moderately acid in the topsoil (pH 6.5-156 5.1 in 1:1 soil: water ratio). With good chemical properties, the soils are fertile and support the 157 production of food and cash crops including cassava, yam, plantain, cocoa, coffee, etc.

### 158 4. METHODOLOGY

### 159 4.1 Sampling and sample technique

160 The stratified sampling technique was used to select the study sample from the study population [16, 161 17]. This technique was chosen in order to evenly spread the sample across the entire population. 162 Stratified sampling ensures a greater degree of representativeness, thereby reducing the probable 163 sampling error. It ensures that different groups of population are adequately represented in the 164 sample. It combines homogeneity and heterogeneity at different levels. With this technique, the study 165 area was divided into five (5) separate groups called strata with residential location as criterion (Figure 166 2). In each stratum, forty (40) respondents were selected by simple random sampling employing the lottery method. The lottery method was done by preparing a list of names and contact details of 150 167 168 persons which constituted the sample frame for a particular stratum. Each person's name was then 169 transferred from the sample frame (that is, the list of 150 persons) and then put onto separate pieces 170 of papers. The pieces of papers were placed in a container and thoroughly mixed. The required number of respondents for a particular stratum (that is, 40), were selected without looking. The names 171 172 selected constituted the simple random sample. The same random sampling procedure, was done for 173 the four (4) other strata.

174

Fig.2. Layout of Abetifi Township showing various strata where respondents were
 randomly selected Source: The Authors, 2018

#### 178 4.2 Primary data collection

179 The study employed a descriptive cross-sectional survey to collect primary data. In all, 200 180 respondents from individual households including institutional bungalows, flats, compound houses, 181 semi-detached houses, etc were contacted and interviewed. Both gualitative and guantitative data 182 were collected from the respondents by the use of a set of validated semi-structured questionnaires.

#### 183 4.3 Data analysis and presentation

The data was keyed into the Statistical Package for the Social Sciences (SPSS) and analyzed using 184 185 the interpretative technique to analyze observation and interview information obtained. The 186 descriptive statistical method was used in summarizing and presenting data in the form of tables and 187 numerical measure (percentages) in an informative way.

#### 188 5. RESULTS AND DISCUSSION

189

190 5.1 Demographic characteristics of respondents

#### 191 5.1.1 Gender of respondents

192 Majority of the respondents interviewed were females represented by a proportion of 54% of the total 193 number of the interviewees as shown in Table 1 below. On the other hand, there was 46% male 194 representation for the study sample. Commonly, women and girls are known to be involved in the 195 handling and management of household water for several domestic purposes. Addressing the needs 196 of females in respect of the quantity and quality of water supply is worth it.

#### 197 Table 1. Gender distribution of respondents

198

Gender of respondents	Number of respondents	Percentage of respondents	
Male	92	46	
Female	108	54	
Total	200	100	

#### 199 Source: Field survey, 2017

#### 200 5.1.2 Age of respondents

201 Majority of the respondents fell under the age group of 31-40 years represented by 34% of the study 202 sample as shown in Table 2 below. This showed that majority of the respondents reached were in the 203 parenting and working ages. Persons in this age group use water for domestic activities at the 204 household level and other socio-economic activities. Moreover, 26% and 22% of the respondents were in the age groups of 21-30 years and 11-20 years respectively. The least of respondents' 205 206 representation in terms of age was the over 40 years age group representing 18% of the study 207 sample. In all, there was a fair representation of all age groups for the study.

208

#### 209 Table 2. Age distribution of respondents

210

Age of respondents (years)	Number of respondents	Percentage of respondents
11-20	44	22
21-30	52	26
31-40	68	34
>40	36	18
Total	200	100

211 Source: Field survey, 2017

#### 213 5.1.3 Duration of residency of respondents

214 Table 3 below indicates that majority of the respondents (24%) have stayed in the study area between 215 31-40 years. Twenty-three percent (23%) and 21% of the respondents have lived in the study area 216 within the periods, less than 10 years and 21-30 years respectively. Eighteen percent (18%) of the 217 respondents have lived in the area within 10-20 years with the least of the respondents (14%) having 218 been residents of the study more than 40 years. The number of years respondents have stayed in the 219 study area was very important in order to obtain information that tells the real situation in terms of 220 water supply during the dry season.

221

#### 222 Table 3. Duration of residency of respondents

223

Duration of residency of respondents (years)	Number of respondents	Percentage of respondents	
<10	46	23	
10-20	36	18	
21-30	42	21	
31-40	48	24	
>40	28	14	
Total	200	100	

224 Source: Field survey, 2017

### 225

#### 226 5.2 Proximity to water supply points

227 Public Stand posts made up of several taps connected to a service line (a borehole) as described by 228 one author [18] and dug wells are primarily patronized by the folks in the study area during the dry 229 season as the available streams are dried up. Some authors [19] describe a reliable service as the 230 one which is easy to access without one going through unnecessary stresses. Results of the study refuted this assertion; water accessibility at supply points in the study area has always been faced 231 232 with challenges during the off-season period. Proximity to stand posts and dug wells have invariably 233 been a major challenge in rural communities for which the study area was not an exemption. In most 234 times, the community people trek long distances before accessing the available water.

235 The study revealed that 16% and 22% of the respondents spent approximately 20 minutes and 35 236 minutes respectively to access water and return to their homes (Table 4). A few (10%) claimed they 237 spent approximately 15 minutes doing same. A relatively larger proportion of the sampled population 238 (52%) rather spent more than 40 minutes to access water from the available supply points and return 239 to their homes. The longer duration could have possibly been attributed to longer distances one has to pursue in accessing water amid queuing times. Those who may find queuing to access water 240 241 frustrating leave their containers in the custody of water sales personnel who man the stand pipes so 242 they could be served in their absence. Despite the fact that such people do not waste time waiting at 243 the water supply point, there is always a longer time before they are able to access the water again in 244 such a water-stress period. The implication is that, households have to manage quantities of water for 245 a period before they could access the water supplies again. Households with larger family sizes are 246 the ones that suffer from this challenge the most.

### 247

248

### Table 4. Duration used in accessing water and returning to homes

-0	
	Duration

Duration for accessing water	Number of respondents	Percentage of respondents	
Appx. 15 minutes	20	10	
Appx. 20 minutes	32	16	
Appx. 35 minutes	44	22	
> 40 minutes	104	52	
Total	200	100	

<sup>249</sup> Source: Field survey, 2017

#### 252 5.3 Wholesomeness of accessed water during the dry season

As shown in Table 5 below, there were different forms by which people in the study area use 255 accessed water. When asked, respondents gave several uses of accessed water. Respondents used accessed water for drinking (19%), cooking (47%), bathing and washing (34%).

256 257 258

259

### Table 5. Uses of water accessed by respondents

Uses of accessed water	Number of respondents	Percentage of respondents	
Drinking	38	19	
Cooking	94	47	
Bathing and washing	68	34	
Total	200	100	

260 Source: Field survey, 2017

261 262 The various uses of accessed water indicated by the respondents were not surprising as the majority 263 of them (68%) claimed the supplied water was good with only a few (32%) making mention of its 264 particulate nature (Table 6). One author [20] attested to the fact that water from dug wells in rural 265 areas have over the time been challenged with the lack of quality tests and as such stands a higher 266 risk of compromising people's health.

267 It is imperative for community water supplies to be of good quality to ensure the safety of consumers 268 [19]. Consequently, researchers [21, 22, 23] have attributed many health challenges and diseases to unhygienic rural water supplies. Very importantly, ensuring supply of good quality water in their right 269 270 quantities safeguards primary health of people as well as socio-economic development [24]. 271 Compromising universal water, sanitation and hygiene is thus not what one would ever wish for.

### 272 Table 6. Perceived quality of available water supply in the study area 273

Perceived water quality	Number of respondents	Percentage of respondents
Good	136	68
Salty	0	0
Bad odour	0	0
Tainted water	0	0
Particulate water	64	32
Total	200	100

274 Source: Field survey, 2017

Globally, approximately 3.5 million deaths and a daily record of 1,000 child mortality occur as a result 276 of unsafe water, poor sanitation and hygiene [25,26]. When the basic water accessibility level is not 277 278 attained, achieving a proper personal hygiene as well becomes very difficult to envisage. Time and 279 distance thus come into play in determining the volumes of water that people are able to access to 280 meet their personal hygiene needs [12]. According to these authors, the levels at which people are 281 able to access water for use can be linked to the assurance of their health (Table 7).

#### 282 Table 7. Summary of requirement for water service level (accessibility) to promote health 283

Service level	Access measure	Needs met	Level of health concern
No access (quantity collected often below 5l/c/d)	More than 1000 m or 30 minutes total collection time	Consumption: cannot be assured. Hygiene: not possible (unless practised at source).	Very high

<sup>275</sup> 

Basic access (average quantity unlikely to exceed 20l/c/d)	Between 100 and 1000 m or 5 to 30 minutes total collection time	Consumption: should be assured. Hygiene: hand washing and basic food hygiene possible; laundry/bathing difficult to assure unless carried out at source	High
Intermediate access (average quantity about 50l/c/d)	Water delivered through one tap on-plot (or within 100 m or 5 minutes total collection time)	Consumption: assured. Hygiene: all basic personal and food hygiene assured; bathing and laundry should also be assured	Low
Optimal access (average quantity 100l/c/d and above)	Water supplied through multiple taps continuously	Consumption: all needs met. Hygiene: all needs should be met.	Very low

285

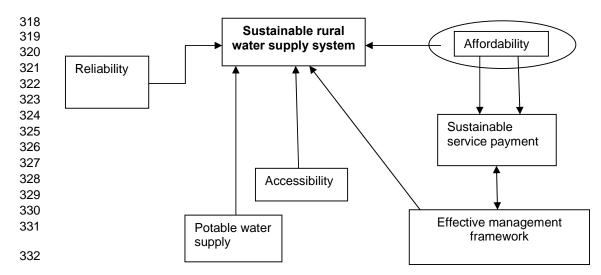

### 286 **5.4 Community water costing and reliability**

Most often, water supply systems have broken down primarily as a result of managerial as well as financial challenges. Researchers have over the years explained and made it clear on the essence of developing a more efficient system. A key factor in ensuring the sustainability of rural water supply systems is the ability and willingness of community people to pay for the service provided. As indicated in figure 3 below, reliable payments for water service will ensure that community water supply management framework works effectively. In that case, such water supplies must be potable, reliable, and easily accessible without spending longer time in accessing them.

The challenge of rural water supply systems sustainability transcends local and regional boundaries. There is however the utmost need for full community involvement and support, in the project during its design, construction and management in order to ensure its sustainability. These when done, would go a long way in ensuring the financial as well as the managerial strength of the system. Good financial management certainly needs to be strictly adhered to in order to cater for the operational and maintenance needs (O&M) of water supply systems and as well ensure their robustness and sustainability (Figure 3).

301 At the time of the study, a 25 litre container full of water cost 40 Ghana pesewas (US\$0.08) with a 30 302 litre container going for 50 Ghana pesewas (US\$0.10) at water stand posts. The respondents 303 however described these prices as fair and were willing to pay without hesitation. Apparently, the 304 volumes of water accessed by the respondents were not affected by cost but perhaps other factors 305 [27]. Some respondents had shown high interest in household connectivity to the Ghana Water 306 Company lines and were ready to pay for bills they would receive from the company if connected to its 307 lines whilst others called for the construction of more mechanized boreholes at vantage points for 308 easy accessibility of the greater majority during the dry season. Apparently, this was in line with [28] 309 who had argued the need to reduce water accessibility distance and encouraged household 310 connections.

# Fig.3. A proposed structure of a sustainable rural water supply system (Source: The Authors, 2018)

### 335 6. SUMMARY OF FINDINGS

(1) Majority of the people (52%, n=200) in the study area spend longer period (more than 40 minutes)
 in accessing water from available supply points before they return to their homes during the dry
 season.

(2) The quality of accessed water in the study area, were perceived to be good (68%, n=200) during
 the dry season.

### 7. CONCLUSION

During the dry season, people in the study area use a lot of time to obtain water from the available 345 346 supplies for use. Sanitation and health aspects of the community folks could be jeopardized because 347 the per capita water consumption at the household level would not be met with this stemming from 348 insufficient water supplies for homes. Moreover, water supply in Abetifi-Kwahu during the dry season 349 is a challenge to the extent that inhabitants who can only afford resort to purchasing water from 350 neighbouring towns that are connected to the Ghana Water Company lines increasing cost of 351 assessing water and consequently living standards during this period. On the other hand, accessed 352 water during this period of the year in the study area, were perceived to be good.

### 353 8. RECOMMENDATION

354

336

342 343

344

355 Water should easily be accessible to all in their sufficient quantities and quality. There is the need for 356 more stand posts and mechanized boreholes to be constructed at vantage points in the study 357 community. Again, household connectivity to water supply lines should be considered, critically 358 assessed and implemented by Government through the Ghana Water Company Limited and all 359 relevant stakeholders. Water quality is very critical in ensuring proper public health and the prevention 360 of water related diseases. It is therefore prudent that water resources used mostly for domestic purposes are highly accessible in their significant quantities and free from all forms of pathogenic 361 362 materials. The authors of this study consequently recommend a study on the assessment of the water 363 quality of the several standpipes, dug wells and ponds which the community people resort to as there 364 is little or no work done in that regard.

### 365 ACKNOWLEDGEMENTS

366

This research did not receive any specific grant from funding agencies in the public, commercial, or not-for-profit sectors. The authors are however thankful to all the enumerators who assisted immensely in the study area stratification and data collection processes. A special thank you goes to Dr. Gifty Seiwaa Nyarko for her immense assistance in the manuscript preparation. Last but not least, 371 the authors are grateful to Mr. Kwaku Karikari Amoah, Head of Institutional Advancement and 372 Consultancy Unit of the Presbyterian University College Ghana for proofreading the manuscript.

475		QUESTIONNAIRE
475		
		RESPONDENTS: COMMUNITY FOLKS IN ABETIFI-KWAHU, GHANA
477		
478	This st	udy is aimed at finding out the opinions of community folks on the characteristics of off-season
479		upplies in Abetifi-Kwahu situated in the Kwahu-East District of Ghana. The study requires your
480		and honest opinion as a participant. As such, this request is voluntary so do not feel forced in
481		y in stating your views.
	, <i></i> u	,

482 The research is purely for academic and development purposes and so your responses are assuredly 483 confidential and anonymity is safeguarded.

484 Thank you for your participation.

INSTRUCTION: Please tick ( $\checkmark$ ) the appropriate answer

#	SECTIONS	RESPONSES	
	Demographics		
1	Gender	<ol> <li>Male</li> <li>Female</li> </ol>	
2	Age at latest birthday	1. 11-20	
		2. 21-30	
		3. 31-40	
		4. More than 40	
3	What is your highest level of education?	1. None	
		2. Primary 1-6	
		3. Middle/JHS	
		4. SSS/Technical	
		5. University/College	
		6. Non-formal	
		7. Others (Specify)	
4	For how many years have you lived in this community?	1. Less than 10	
		2. 10-20	
		3. 21-30	
		4. 31-40	
		5. More than 40	
	Water supply issues		
5	What are the available water sources you have in your	1. Borehole	
	community?	2. Dug well	
		3. Stream	
		4. Pond	
		5. Others (Specify)	
6	Are all available water sources in your community accessible during the dry season?	1. Yes 2. No	
7	What are the available water	1. Borehole	
	sources you have in your		

		-	<b>D</b>
	community during the dry season period?	2.	Dug well
		3.	Stream
		4.	Pond
		5.	Others (Specify)
8	In your view, do you feel there are challenges with accessing	1.	Yes
	water sources in your community during the dry season period?	2.	No
9	What is the proximity to available water sources in your	1.	Closer to my house
	community during the dry season?	2.	Far away from my house
	3643011:	3.	Others (Specify)
10	Is the number of water sources	1.	Yes
	available to you during the dry season period adequate?	2.	No
11	Do you queue to access	1.	Yes
	available water sources in your community during the dry season?	2.	No
12	In your view, approximately how	1.	15 minutes
	many minutes do you use to access available water sources and return to your home?	2.	20 minutes
		3.	35 minutes
		4.	More than 40 minutes
	<b>N</b>		
13	Perceived water quality and healt How do you perceive the quality		s Good
	of the available water sources during the dry season?		Salty
		3.	Bad odour
		4.	Tainted water
		5.	Particulate water
14	What is your UTMOST use of	1.	Drinking
	the water you are able to access during the dry season period?	2.	Cooking
		3.	Bathing and washing

		r						
15	Have you ever been taken ill	1.	Yes					
	after ingesting the available							
	water during the dry season?	2.	No					
	Community water easting and reliability							
16	Community water costing and reliability							
10	In your view, do you think it is affordable to access water	1.	Yes					
	sources during the dry season?	2	No					
	sources during the dry season?	۷.	110					
17	In your view, do you think it is	1.	Yes					
	affordable to access water at							
	stand pipes in your community	2.	No					
	during the dry season?							
18	What is the cost of water at							
	community stand pipes during							
	the dry season?							
19	Do the community stand pipes	1.	Yes					
19	frequently break down during	1.	Tes					
	the dry season?	2	No					
		2.						
20	In your view, do you think the	1.	Yes					
	management of the operations							
	and maintenance of stand pipes	2.	No					
	in your community is good?							
21	Are you always willing to pay for	1.	Yes					
	the water supply service in your	2	No					
	community?	Ζ.	No					
22	Would you prefer household	1.	Yes					
	water connectivity in your							
	community?	2.	No					
	-							
23	Will you be willing to pay for bills	1.	Yes					
	you will receive from the Ghana							
	Water Company after you have	2.	No					
	been connected to household							
	connection?
