

Validation of the Alere™ Methamphetamine Microplate ELISA for the detection of Methamphetamine in oral fluid

ABSTRACT

Abuse of methamphetamine is one of the major social problem faced by many countries. Despite the ban on the use of methamphetamine, it is still available in some UK's drug shops. Oral fluid as an alternative matrix for assessing drugs of abuse is gaining prominence. It is therefore important to investigate assay performance and limitations of screening techniques for methamphetamine in oral fluid. The purpose of this study was to evaluate the validity of Alere™ methamphetamine microplate competitive enzyme linked immunosorbent assay (ELISA) for the analysis of methamphetamine in oral fluid. Ten samples were analysed in the laboratory using the Alere™ Methamphetamine ELISA kit and the results were compared to the results obtained using gas chromatography-mass spectrometry(GC-MS) with good precisions (intra = 2.88%, inter = 9.04%) and accuracy ($R^2 = 0.9975$). True negative, true positive, false negative and false positive results were determined in relation to the GC-MS analysis. The result of the samples consisted 6 true negatives, 3 true positives and 1 false negative within the cut off concentration of 100 ng/mL. The results also demonstrated a functional sensitivity and specificity of 75% and 100% respectively. All the tested cross reactive drugs showed cross reactivity of less than 10% with methamphetamine except for MDMA which showed cross reactivity of 44%. These data show that Alere™ methamphetamine microplate ELISA is a fast, precise and accurate screening technique for the detection of methamphetamine in oral fluid samples.

Keywords: Methamphetamine; ELISA; Oral fluid; Cross reactivity

1. INTRODUCTION

Methamphetamine (METH) is a potent stimulant that affects the central nervous system. It was synthesized through the methylation of amphetamine, making it easy for permeation into the blood stream and brain [1-2]. METH, among other amphetamine derivatives is the most widely abused drug because of its high potency. At comparable doses, larger amount of it gets into the brain making it a more potent stimulant than others, including the parent amphetamine, thus making it a highly abused drug and hence causing peripheral sympathomimetic activity [3-4]. Therefore, a fast and accurate screening method of these drugs in biological matrices is of great importance.

39 According to 2013 NIDA report series, METH can be administered via injection, inhalation
40 or oral ingestion and smoking depending on the forms, with a slower occurrence effect from
41 oral administration. Injection and smoking are the common ways through which METH is
42 administered, as these methods easily get the drug into the brain and bloodstream, creating an
43 instant drug's addition potential as well as health consequences [3].

44 The screening for METH abuse is said to be complicated, as analogues drugs such as
45 methylenedioxyamphetamine (MDMA), methylenedioxyamphetamine (MDA),
46 methylenedioxyethylamphetamine (MDEA) and D-amphetamine have been used by abusers
47 of METH to mimic its effects [5]. Kroener & Musshoff reported that most of these analogue
48 drugs are likely to test positive by some commercial immunoassay screening for METH [6].

49 The analysis of METH and its related drugs has recently involved the use of enzyme linked
50 immunosorbent assay (ELISA) in most forensic laboratories [7-8]. This is due to its
51 adaptability for use with urine, oral fluid and blood samples without sample pre-treatment;
52 ease to use, low volume applicability and growing potential for automation [7]. ELISA relies
53 on the inherent ability of an antibody to bind to the specific structure of a molecule.

54 The use of oral fluid as an alternative matrix to blood and urine for the assessment of drug
55 status is on the increase. Oral fluid is readily available for collection and non-invasive with
56 nominal chance of adulteration when compared with blood and urine [9-10]. A similar study
57 reported a low accumulation of MDMA in plasma after administration of 75 mg of MDMA
58 than in oral fluid, with concentrations of 21-295 $\mu\text{g/L}$ and 50-6982 $\mu\text{g/L}$ for plasma and oral
59 fluid respectively [11]. Also, reviewed studies by de la Torre *et al.* on the clinical
60 pharmacokinetics showed a higher concentration of MDMA in oral fluid than in other
61 matrices [12]. Nevertheless, the administrative routes and collection procedure can greatly
62 affect the detection concentrations in oral fluid [8].

63 The purpose of this study was to evaluate the validity of AlereTM METH microplate ELISA
64 as a screening method for the detection of METH in oral fluid samples, since drugs detection
65 in biological matrices have legal implications. The results obtained using ELISA were
66 compared to a reference data obtained from GC-MS. The accuracy of the assay was
67 determined and the functional sensitivity and specificity of the assay were calculated.

68

69 **2. MATERIALS AND METHODS**

70 **2.1 Materials**

71

72 **2.1.1 Reagents and chemicals**

73 AlereTM ELISA kit used for the METH screening contained the following; a ninety-six (96)
74 well antibody coated micro strips, wash buffer solution of 0.1 %(v/v) surfactant, enzyme
75 conjugated to horseradish peroxidase (HRP), substrate solution (3,3',5,5'-
76 tetramethylbenzidine) (TMB) and stopping solution (1.0 M sulphuric acid). 500 ng/mL
77 MDMA, 500 ng/mL D-amphetamine, 500 ng/mL MDA and 500 ng/mL MDEA were used to

78 test for cross reactivity to METH. Four calibrators (standard solutions) (0, 25, 100 and 500
79 ng/mL) of METH in oral fluid were used. All the chemicals and reagents were of analytical
80 grade and gotten from Sigma Aldrich, United Kingdom.

81

82 **2.1.2 Apparatus**

83 Microplate reader ELX800, multi channelled pipette, an automated pipette, a Guardian
84 centrifuge, sterile Eppendorf tubes (1.5 mL), sterile trough, Eppendorf rack and fisher brand
85 wash bottle were all used for this study.

86

87 **2.1.3 Samples**

88 10 oral fluid samples were obtained from a sample bank of Biosciences laboratory, Sheffield
89 Hallam University, UK. The samples were collected using Quantisal oral fluid collection
90 device according to the manufacturer's instruction. The samples were stored at -20 °C prior to
91 analysis, after which the samples were tested and screened at Sheffield Hallam University,
92 Bioscience laboratory for METH. The negative control sample was collected and stored at -
93 20 °C prior to analysis following the same sample collection procedure as above. The drug
94 free oral fluid sample was used as negative control while a positive control sample of 100
95 ng/mL in oral fluid was prepared by the addition of 100 µL of working solution of METH at
96 1000 ng/mL to 900 µL of drug free oral fluid.

97

98

99 **2.2 Methods**

100

101 **2.2.1 AlereTM Methamphetamine Microplate ELISA**

102

103 The ELISA screening used in this research is a competitive heterogeneous enzyme
104 immunosorbent assay. The calibrators were placed in front and at the extreme of the 96 well
105 plate, followed by the control samples, cross reactive samples, the test samples and the
106 linearity samples. The calibrators were analysed four times while the rest samples were
107 analysed in duplicate. 25 µL each of the above listed samples were pipetted into the 96 well
108 plate. 100 µL of the enzyme conjugate was added to each of the wells and the mixture was
109 incubated for 30 minutes at ambient temperature. After the period of incubation was over, the
110 wells were washed four times with 300 µL of the wash buffer to remove any unbound antigen
111 sample. This was followed by the addition of 100 µL TMB substrate solution and the mixture
112 was further incubated for 30 minutes at ambient temperature. This gave a varying degree of
113 blue colouration depending on the concentration of methamphetamine in each well. Finally,
114 the reaction was brought to a stop by adding 100 µL of the stop solution. The blue content of
115 the wells turned yellow upon the addition of the stop solution. This yellow colouration
116 enables the multi well plate reader to detect the chromophore at 450 nm, after which the
117 absorption was measured at 450 nm within 30 minutes using ELX800 microplate ELISA
118 reader. From the calibration curve obtained by plotting the calibrators concentrations against
119 their respective absorbance, the corresponding methamphetamine concentrations were
120 estimated [2].

120

121

122 **2.3 Method validation**

123

124 **2.3.1 Accuracy and Precision**

125 The accuracy of the assay was determined by comparing the measured ELISA results to the
126 reference value obtained from GC-MS. Accuracy as used here is the closeness of agreement
127 between the test results and the reference values [13].

128 The intra-assay (within a day) and inter-assay (between days for two weeks) precisions were
129 calculated using coefficient of variation (CV) from 10 replicate analyses of the 100 ng/mL
130 positive control sample of the oral fluid.

131

132

133

134 **2.3.2 Functional Sensitivity and Specificity**

135 From the comparison of the ELISA results and GC-MS results, the true positive (TP), true
136 negative (TN), false positive (FP) and false negative (FN) at the cut off concentration of 100
137 ng/mL were determined. The TP and FN rate were used to calculate the sensitivity of the
138 assay using equation 1. While the TN and FP rate were used to determine the specificity of
139 the assay using equation 2 [2,14].

140

$$141 \text{ Sensitivity} = \frac{\text{TP}}{\text{TP} + \text{FN}} \times 100$$

142 1

143

$$144 \text{ Specificity} = \frac{\text{TN}}{\text{TN} + \text{FP}} \times 100$$

145 2

146

147 **2.3.3 Cross Reactivity**

148 The extent to which other drug substances cross-react with the immobilised antibody used for
149 the analysis of METH was calculated by testing solutions of MDMA, D-amphetamine, MDA
150 and MDEA in duplicate at 500 ng/mL concentrations. The percentage cross reactivity was
151 calculated by comparison of the measured concentrations with the actual concentrations of
152 the cross reactants expressed in percentage [2,15].

153

154 **2.3.4 Limit of detection (LOD)**

155 The LOD of the assay was determined by measuring the negative control sample twenty times in
156 a single assay. It was calculated from the mean absorbance value by applying equation 3, which
157 yielded an absorbance value which was extrapolated from the calibrator's curve to give the LOD
158 of the assay [2,16].

$$159 \text{ LOD} = A_0 - 2.5\sigma$$

160 3

161 A_0 = Mean absorbance and σ = absorbance standard deviation

162

163 **2.3.5 Linearity**

164 Three concentrations of METH at 8.33 ng/mL, 16.67 ng/mL and 25 ng/mL were prepared by
 165 linear dilution of 25 μ L, 50 μ L and 75 μ L of the stock solution (50 ng/mL) to 150 μ L
 166 respectively with deionized water. The samples were analysed in duplicate to determine the
 167 linearity of the assay. The linear regression analysis is used to establish the relationship
 168 between the instrumental response (y) and the analyte concentration (x).

169

170 2.4 GC-MS Analysis

171 The GC-MS used for this study was an Agilent 7890A with 5975C run in electron impact
 172 mode, split-less injection and equipped with Restek Rtx®-5MS capillary column of 30 m,
 173 0.25 mm and 0.25 μ m. The injection port temperature was 250 °C with injection volume of
 174 1.0 μ L and carrier gas flow rate of 1.0 mL/min. The temperature programme consisted of
 175 initial temperature of 60 °C at 1 min which was ramped at 10 °C/min to 220 °C and then held
 176 for 4 min.

177

178 3. RESULTS AND DISCUSSION

179 The high level of abuse of METH in recent time has called for rapid growth in forensic and
 180 clinical analyses. It is therefore important to investigate immunoassay performance and
 181 limitations for drugs of abuse in different biological matrices.

182 The mean absorbance and percent coefficient of variation (%CV) of the calibrators provided
 183 by the assay are shown in Table 1.

184 In this study, a ready to use and reliable METH kit under routine laboratory conditions was
 185 used. This is due to the time consuming optimisation of the calibrators to obtain the expected
 186 absorbance as indicated on the Alere™ methamphetamine ELISA kit instructions. The
 187 generated absorbance was used to validate the assay for qualitative results as it is difficult to
 188 achieve reliable quantitative results with immunoassay [6]. In addition, 1:5 dilution of the
 189 oral fluid samples in water was carried out to reduce background noise [2].

190

191 Table 1: Absorbance of calibrators in the Alere™ methamphetamine ELISA kit

192

	Calibrator			
Conc (ng/mL)	0.00	25.00	100	500
Mean \pm SD	0.75 \pm 0.05	0.36 \pm 0.03	0.16 \pm 0.02	0.06 \pm 0.01
CV (%)	6.76	8.53	10.36	12.98

195

196 3.1 Accuracy and precisions

197 The ELISA results obtained for the ten test samples and the corresponding GC-MS results as
 198 reference standard were compared to ascertain the accuracy and validity of the assay as
 199 shown in Figure 1. The linear regression of 0.9975 obtained from the graph comparing both
 200 ELISA and GC-MS results showed that there is a close correlation between the two
 201 techniques. Also, the negative and positive control samples were confirmed negative and
 202 positive respectively by GC-MS at their cut off concentration.

203 The intra and inter assays precision of the Alere™ methamphetamine ELISA for 10
 204 replicates of positive control sample at 100 ng/mL METH was calculated from the estimated
 205 mean absorbance of 0.13 ± 0.00 (2.88%) and 0.16 ± 0.01 (9.04%) respectively. The intra and
 206 inter assay precision of the test samples were below 10% (Table 2).

207

208

209 Figure 1: Comparative graph of GC-MS and ELIS

210

211 Table 2: Precision of positive control in the Alere™ methamphetamine ELISA kit

Precision	Mean±SD	CV(%)
Intra assay	0.13 ± 0.00	2.88
Inter assay	0.16 ± 0.01	9.04

212

213

214 3.2 Functional sensitivity and specificity

215 The sensitivity and specificity of the assay at a cut off concentration of 100 ng/mL is shown
 216 in Table 3. Of the ten oral fluid samples tested, 60% were confirmed negative (the samples
 217 produced both negative screening and confirmation results), 30% positive (they produced
 218 both positive screening and confirmation results) and 10% was false negative (the sample
 219 produced negative screening and positive confirmation result) within the cut off
 220 concentration of 100 ng/mL. The sensitivity and specificity are necessary for validation, as
 221 they provide insight to the ability of the assay to categorize samples as negative or positive.
 222 The sensitivity obtained was 75% and the specificity was 100%. The specificity obtained was
 223 excellent, but the limitation in sensitivity at the cut off concentration was due to the false
 224 result produced in this study.

225

226

227

228

229

230 Table 3: Sensitivity and specificity of the Alere™ methamphetamine ELISA kit

S/N	ELISA (ng/mL)	GC-MS (ng/mL)	Result
1	19	15	TN
2	42	40	TN
3	280	300	TP
4	3.5	5	TN
5	35	25	TN
6	130	150	TP
7	1.6	00	TN
8	8	10	TN
9	400	450	TP
10	90	110	FN
Sensitivity (%)		75	
Specificity (%)		100	

231 TP = True Positive, FP = False Positive, TN = True Negative, FN = False Negative

232

233 **3.3 Cross Reactivity**

234 The cross reactivities for the Alere™ methamphetamine microplate ELISA screening is given
 235 in Table 4. All the drugs tested showed zero or little cross reactivities of less than 10% with
 236 METH with an exception of MDMA which showed cross reactivity of 44%. This is in line
 237 with the Cozart® methamphetamine microplate ELISA having approximately 50% cross
 238 reactivity with MDMA [8]. This could be due to the ability of the antibody immobilised on
 239 the microplate to recognise MDMA having structural molecule similar to METH molecule
 240 [15]. These discoveries were important in order to distinguish between METH and other
 241 closely related drugs as; these drugs are capable of producing false positive results in the
 242 reflection of METH. Although ELISA technique could be considered as being specific to the
 243 analyte of interest(METH). However, there was a significant cross reactivity with MDMA
 244 drug. Therefore, it is important to have a screening that is as specific as possible for METH.
 245

246 Table 4: Relative cross reactivities of Alere™ methamphetamine ELISA with
247 methamphetamine

Drug Conc. (ng/mL)	Compound	Measured Conc. (ng/mL)	Percent cross reactivity (%)
500	MDMA	220	44
500	D-Amphetamine	ND	ND
500	MDA	38	7.6

500	MDEA	1.3	0.26
-----	------	-----	------

248

249

250 3.4 Limit of detection (LOD) and Linearity

251 The LOD of the assay was calculated to be 1.6 ng/mL, and the mean absorbance of the
252 twenty replicates of the negative control sample was 0.74 ± 0.02 standard deviation.

253 The AlereTM methamphetamine microplate ELISA assay, shows good linearity with
254 regression coefficient (R^2) of 0.9998 as shown in Figure 2.

255

256 Figure 2: Linear graph correlating measured and actual concentration of METH using ELISA
257 kit

258

259 4. CONCLUSION

260 A screening technique for the detection of methamphetamine in oral fluid has been validated.
261 In general, the results show that the AlereTM methamphetamine microplate ELISA is specific,
262 rapid and accurate for screening METH positive oral fluid sample. However, there was a
263 significant cross reactivity with MDMA drug. Cross reactivity tendencies in ELISA
264 technique could be regarded as a major setback since results obtained have to be further
265 confirmed using a more specific technique like GC-MS. Therefore, ELISA technique should
266 be validated for each type of drugs in different matrices.
