6
7
8
9 **ABSTRACT**

10 Abuse of methamphetamine is one of the major social problem faced by many countries. Oral
11 fluid as an alternative matrix for assessing drugs of abuse is gaining prominence. It is
12 therefore essential to investigate assay performance and limitations of screening techniques
13 for methamphetamine in oral fluid. The purpose of this study was to evaluate the validity of
14 Alere™ methamphetamine microplate competitive enzyme-linked immunosorbent assay
15 (ELISA) for the analysis of methamphetamine in oral fluid. Ten samples were analysed in the
16 laboratory using the Alere™ Methamphetamine ELISA kit, and the results were compared to
17 the results obtained using gas chromatography-mass spectrometry(GC-MS) with good
18 precisions (intra = 2.88%, inter = 9.04%) and accuracy ($R^2 = 0.9975$). True negative, true
19 positive, false negative and false positive results were determined by the GC-MS analysis.
20 The result of the samples consisted 6 true negatives, 3 true positives and 1 false negative
21 within the cut off concentration of 100 ng/mL. The results also demonstrated a functional
22 sensitivity and specificity of 75% and 100% respectively. All the tested cross-reactive drugs
23 showed cross-reactivity of less than 10% with methamphetamine except for MDMA which
24 showed cross-reactivity of 44%. These data show that Alere™ methamphetamine microplate
25 ELISA is a fast, precise and accurate screening technique for the detection of
26 methamphetamine in oral fluid samples.

28
29 **1. INTRODUCTION**

30 Methamphetamine (METH) is a potent stimulant that affects the central nervous system. It
31 was synthesised through the methylation of amphetamine, making it easy for permeation into
32 the blood stream and brain [1-2]. METH, among other amphetamine derivatives, is the most
33 widely abused drug because of its high potency. At comparable doses, a larger amount of it
34 gets into the brain making it a more potent stimulant than others, including the parent
35 amphetamine, thus making it a highly abused drug and hence causing peripheral
36 sympathomimetic activity [3-4]. Therefore, a fast and accurate screening method of these
37 drugs in biological matrices is of great importance.

39 Methamphetamine hydrochloride (crystal METH) which is the widely used form, exists as
40 white crystals or crystalline powder at room temperature with a bitter taste and has a melting
41 point between 170-175 °C and it is soluble in water and ethanol. METH decomposes on
42 heating, emitting toxic vapour of nitric oxides but stable under acidic and basic conditions
43 [5]. METH can be oxidized by human Flavin-Containing Monooxygenase Form 3 (FMO3) to
44 methamphetamine hydroxylamine which in turn can be oxidized to phenylpropanoid by
45 FMO3 [6].

46
47 According to 2013 national institute of drug abuse (NIDA) report series, METH can be
48 administered via injection, inhalation or oral ingestion and smoking depending on the forms,
49 with a slower occurrence effect from oral administration. Injection and smoking are the
50 common ways through which METH is administered, as these methods easily get the drug
51 into the brain and bloodstream, creating an instant drug's addiction potential as well as health
52 consequences [3].

53 The screening for METH abuse is said to be complicated, as analogues drugs such as
54 methylenedioxymethamphetamine (MDMA), methylenedioxyamphetamine (MDA),
55 methylenedioxymethamphetamine (MDEA) and D-amphetamine have been used by abusers
56 of METH to mimic its effects [7]. Kroener & Musshoff reported that most of these analogue
57 drugs are likely to test positive by some commercial immunoassay screening for METH [8].

58 The analysis of METH and its related drugs has recently involved the use of enzyme-linked
59 immunosorbent assay (ELISA) in most forensic laboratories [9-10]. This is due to its
60 adaptability for use with urine, oral fluid and blood samples without sample pre-treatment;
61 ease to use, low volume applicability and growing potential for automation [9]. ELISA relies
62 on the inherent ability of an antibody to bind to the specific structure of a molecule.

63 The use of oral fluid as an alternative matrix to blood and urine for the assessment of drug
64 status is on the increase. Oral fluid is readily available for collection and non-invasive with a
65 nominal chance of contamination when compared with blood and urine [11-12]. A similar
66 study reported a low accumulation of MDMA in plasma after administration of 75 mg of
67 MDMA than in oral fluid, with concentrations of 21-295 µg/L and 50-6982 µg/L for plasma
68 and oral fluid respectively [13]. Also, reviewed studies by de la Torre *et al.* on the clinical
69 pharmacokinetics showed a higher concentration of MDMA in oral fluid than in other
70 matrices [14]. Nevertheless, the administrative routes and collection procedure can greatly
71 affect the detection concentrations in oral fluid [10].

72 The purpose of this study was to evaluate the validity of Alere™ METH microplate ELISA
73 as a screening method for the detection of METH in oral fluid samples since drugs detection
74 in biological matrices has legal implications. The results obtained using ELISA were
75 compared to a reference data collected from GC-MS. The accuracy of the assay was
76 determined, and the functional sensitivity and specificity of the test were calculated.

77

78 2. MATERIALS AND METHODS

79 **2.1 Materials**

80

81 **2.1.1 Reagents and chemicals**

82 Alere™ ELISA kit used for the METH screening contained the following; a ninety-six (96)
83 well antibody coated micro strips, wash buffer solution of 0.1 %(v/v) surfactant, enzyme
84 conjugated to horseradish peroxidase (HRP), substrate solution (3,3',5,5'-
85 tetramethylbenzidine) (TMB) and stopping solution (1.0 M sulphuric acid). 500 ng/mL
86 MDMA, 500 ng/mL D-amphetamine, 500 ng/mL MDA and 500 ng/mL MDEA were used to
87 test for cross-reactivity to METH. Four calibrators (standard solutions) (0, 25, 100 and 500
88 ng/mL) of METH in oral fluid were used. All the chemicals and reagents were of analytical
89 grade and gotten from Sigma Aldrich, United Kingdom.

90

91 **2.1.2 Apparatus**

92 Microplate reader ELX800, multi-channelled pipette, an automated pipette, a Guardian
93 centrifuge, sterile Eppendorf tubes (1.5 mL), sterile trough, Eppendorf rack and Fisher brand
94 wash bottle were all used for this study.

95

96 **2.1.3 Samples**

97 10 oral fluid samples were obtained from the sample bank of Biosciences laboratory,
98 Department of Biosciences and Chemistry, Sheffield Hallam University, UK. The samples
99 were collected using Quantisal oral fluid collection device according to the manufacturer's
100 instruction and were stored at -20 °C. The samples were tested and screened at Sheffield
101 Hallam University, Bioscience laboratory for METH. The negative control sample was also
102 obtained as above. The drug-free oral fluid sample was used as a negative control while a
103 positive control sample of 100 ng/mL in oral fluid was prepared by the addition of 100 µL of
104 working solution of METH at 1000 ng/mL to 900 µL of drug-free oral fluid.

105

106

107 **2.2 Methods**

108

109 **2.2.1 Alere™ Methamphetamine Microplate ELISA**

110 The ELISA screening used in this research is a competitive heterogeneous enzyme
111 immunosorbent assay. The calibrators were placed in front and at the extreme of the 96 well
112 plate, followed by the control samples, cross-reactive samples, the test samples and the
113 linearity samples. The calibrators were analysed four times while the rest samples were
114 analysed in duplicate. 25 µL each of the above-listed samples were pipetted into the 96 well
115 plate. 100 µL of the enzyme conjugate was added to each of the wells, and the mixture was
116 incubated for 30 minutes at ambient temperature. After the period of incubation was over, the
117 wells were washed four times with 300 µL of the wash buffer to remove any unbound antigen
118 sample. This was followed by the addition of 100 µL TMB substrate solution and the mixture
119 was further incubated for 30 minutes at ambient temperature. This gave a varying degree of
120 blue colouration depending on the concentration of methamphetamine in each well. Finally,
121 the reaction was brought to a stop by adding 100 µL of the stop solution. The blue content of
122 the wells turned yellow upon the addition of the stop solution. This yellow colouration

123 enables the multi-well plate reader to detect the chromophore at 450 nm, after which the
124 absorption was measured at 450 nm within 30 minutes using ELX800 microplate ELISA
125 reader. From the calibration curve obtained by plotting the calibrators concentrations against
126 their respective absorbance, the corresponding methamphetamine concentrations were
127 estimated [2].

128
129

130 **2.3 Method validation**

131

132 **2.3.1 Accuracy and Precision**

133 The accuracy of the assay was determined by comparing the measured ELISA results to the
134 reference value obtained from GC-MS. Accuracy, as used here, is the closeness of agreement
135 between the test results and the reference values [15].

136 The intra-assay (within a day) and inter-assay (between days for two weeks) precisions were
137 calculated using the coefficient of variation (CV) from 10 replicate analyses of the 100
138 ng/mL positive control sample of the oral fluid.

139
140
141

142 **2.3.2 Functional Sensitivity and Specificity**

143 From the comparison of the ELISA results and GC-MS results, the true positive (TP), true
144 negative (TN), false positive (FP) and false negative (FN) at the cut off concentration of 100
145 ng/mL were determined. The TP and FN rate was used to calculate the sensitivity of the assay
146 using equation 1. While the TN and FP rate was used to determine the specificity of the assay
147 using equation 2 [2,16].

148

$$149 \text{ Sensitivity} = \frac{\text{TP}}{\text{TP} + \text{FN}} \times 100$$

150 1

151

$$152 \text{ Specificity} = \frac{\text{TN}}{\text{TN} + \text{FP}} \times 100$$

153 2

154

155 **2.3.3 Cross-Reactivity**

156 The extent to which other drug substances cross-react with the immobilised antibody used for
157 the analysis of METH was calculated by testing solutions of MDMA, D-amphetamine, MDA
158 and MDEA in duplicate at 500 ng/mL concentrations. The percentage cross-reactivity was
159 calculated by comparison of the measured concentrations with the actual levels of the cross
160 reactants expressed in percentage [2,17].

161

162 **2.3.4 Limit of detection (LOD)**

163 The LOD of the assay was determined by measuring the negative control sample twenty times in
164 a single assay. It was calculated from the mean absorbance value by applying equation 3, which
165 yielded an absorbance value which was extrapolated from the calibrator's curve to give the LOD
166 of the assay [2,18].

$$\text{LOD} = \frac{A_0}{3} - 2.5\sigma$$

A_0 = Mean absorbance and σ = absorbance standard deviation

170

171 **2.3.5 Linearity**

172 Three concentrations of METH at 8.33 ng/mL, 16.67 ng/mL and 25 ng/mL were prepared by
 173 successive dilution of 25 μ L, 50 μ L and 75 μ L of the stock solution (50 ng/mL) to 150 μ L
 174 respectively with deionised water. The samples were analysed in duplicate to determine the
 175 linearity of the assay. The linear regression analysis is used to establish the relationship
 176 between the necessary response (y) and the analyte concentration (x).

177

178 **2.4 GC-MS Analysis**

179 The GC-MS used for this study was an Agilent 7890A with the 5975C run in electron impact
 180 ionisation mode, split-less injection and equipped with Restek Rtx®-5MS capillary column
 181 of 30 m, 0.25 mm and 0.25 μ m. The injection port temperature was 250 °f with an injection
 182 volume of 1.0 μ L. Helium was used as the carrier gas at a flow rate of 1.0 mL/min. The
 183 column temperature programme consisted of the initial temperature of 60 °C at 1 min which
 184 was ramped at 10 °C/min to 220 °C and then held for 4 min.

185

186 **3. RESULTS AND DISCUSSION**

187 The high level of abuse of METH in recent time has called for rapid growth in forensic and
 188 clinical analyses. It is therefore important to investigate immunoassay performance and
 189 limitations for drugs of abuse in different biological matrices.

190 The mean absorbance and percent coefficient of variation (%CV) of the calibrators provided
 191 by the assay are shown in Table 1.

192 In this study, a ready to use and reliable METH kit under routine laboratory conditions was
 193 used. This is due to the time-consuming optimisation of the calibrators to obtain the expected
 194 absorbance as indicated on the Alere™ methamphetamine ELISA kit instructions. The
 195 generated absorbance was used to validate the assay for qualitative results as it is difficult to
 196 achieve reliable quantitative results with immunoassay [8]. Also, 1:5 dilution of the oral fluid
 197 samples in water was carried out to reduce background noise [2].

198

199 Table 1: Absorbance of calibrators in the Alere™ methamphetamine ELISA kit

200

	Calibrator				
201	Conc (ng/mL)	0.00	25.00	100	500
202	Mean±SD	0.75±0.05	0.36±0.03	0.16±0.02	0.06±0.01
	CV (%)	6.76	8.53	10.36	12.98

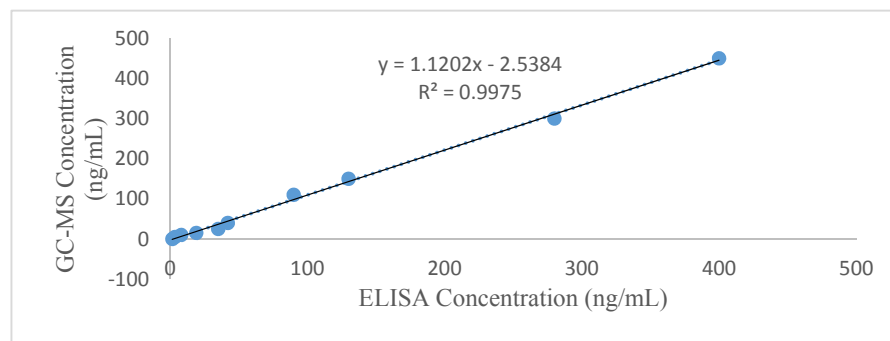

203

204 **3.1 Accuracy and precisions**

205 The ELISA results obtained for the ten test samples and the corresponding GC-MS results as
 206 reference standard were compared to ascertain the accuracy and validity of the assay as
 207 shown in Figure 1 and 2. From Figure 1, the linear regression of 0.9975 obtained from the
 208 graph by comparing both ELISA and GC-MS results showed that there is a close correlation
 209 between the two techniques. Also, the negative and positive control samples were confirmed
 210 negative and positive respectively by GC-MS at their cut off concentration.

211 The intro and inter assays precision of the Alere™ methamphetamine ELISA for ten
 212 replicates of positive control sample at 100 ng/mL METH was calculated from the estimated
 213 mean absorbance of 0.13±0.00 (2.88%) and 0.16±0.01 (9.04%) respectively. The intro and
 214 inter assay precision of the test samples were below 10% (Table 2).

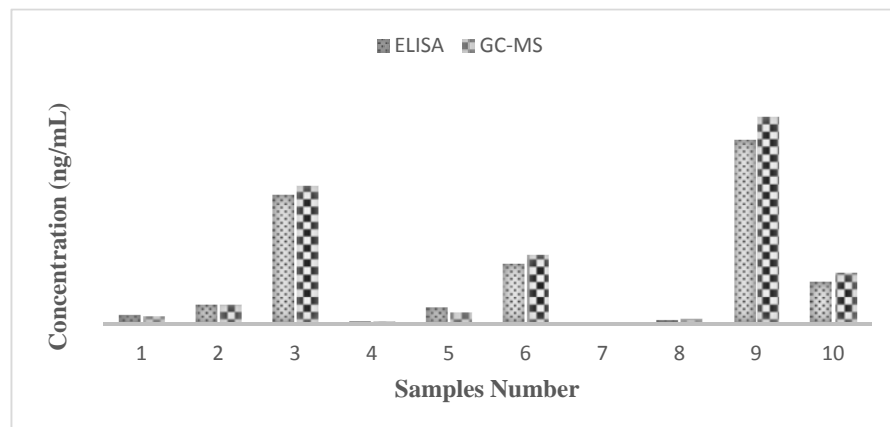

215

221

222

223

224 Table 2: Precision of positive control in the Alere™ methamphetamine ELISA kit

Precision	Mean±SD	CV(%)
Intra assay	0.13±0.00	2.88

Inter-assay 0.16±0.01 9.04

225
226

227 3.2 Functional sensitivity and specificity

228 The sensitivity and specificity of the assay at a cut off concentration of 100 ng/mL is shown
229 in Table 3. Of the ten oral fluid samples tested, 60% were confirmed negative (the samples
230 produced both negative screening and confirmation results), 30% positive (they produced
231 both positive screening and confirmation results) and 10% was false negative (the sample
232 produced negative screening and positive confirmation result) within the cut off
233 concentration of 100 ng/mL. The sensitivity and specificity are necessary for validation, as
234 they provide insight into the ability of the assay to categorize samples as negative or positive.
235 The sensitivity obtained was 75%, and the specificity was 100%. The specificity obtained
236 was excellent, but the limitation in sensitivity at the cut off concentration was due to the false
237 result produced in this study.

238

239 Table 3: Sensitivity and specificity of the AlereTM methamphetamine ELISA kit

S/N	ELISA (ng/mL)	GC-MS (ng/mL)	Result
1	19	15	TN
2	42	40	TN
3	280	300	TP
4	3.5	5	TN
5	35	25	TN
6	130	150	TP
7	1.6	00	TN
8	8	10	TN
9	400	450	TP
10	90	110	FN
Sensitivity (%)	75		
Specificity (%)	100		

240 TP = True Positive, FP = False Positive, TN = True Negative, FN = False Negative

241

242 3.3 Cross-Reactivity

243 The cross reactivities for the AlereTM methamphetamine microplate ELISA screening is given
244 in Table 4. All the drugs tested showed zero or little cross reactivities of less than 10% with
245 METH with an exception of MDMA which showed cross-reactivity of 44%. This is in line

246 with the Cozart[®] methamphetamine microplate ELISA having approximately 50% cross-
 247 reactivity with MDMA [9]. This could be due to the ability of the antibody immobilised on
 248 the microplate to recognise MDMA having structural molecule similar to METH molecule
 249 [17]. These discoveries were important to distinguish between METH and other closely
 250 related drugs as; these drugs are capable of producing false positive results in the reflection of
 251 METH. Although ELISA technique could be considered as being specific to the analyte of
 252 interest(METH). However, there was a significant cross-reactivity with MDMA drug.
 253 Therefore, it is important to have a screening that is as specific as possible for METH.
 254

255 Table 4: Relative cross reactivities of Alere[™] methamphetamine ELISA with
 256 methamphetamine

Drug Conc. (ng/mL)	Compound	Measured Conc. (ng/mL)	Percent cross-reactivity (%)
500	MDMA	220	44
500	D-Amphetamine	ND	ND
500	MDA	38	7.6
500	MDEA	1.3	0.26

257

258

259 3.4 Limit of detection (LOD) and Linearity

260 The LOD of the assay was calculated to be 1.6 ng/mL, and the mean absorbance of the
 261 twenty replicates of the negative control sample was 0.74±0.02 standard deviation.

262 The Alere[™] methamphetamine microplate ELISA assay shows good linearity with
 263 regression coefficient (R^2) of 0.9998 as shown in Figure 2.

264

265 Figure 3: Linear graph correlating measured and actual concentration of METH using ELISA
 266 kit

267

268 4. CONCLUSION

269 A screening technique for the detection of methamphetamine in oral fluid has been validated.
270 In general, the results show that the Alere™ methamphetamine microplate ELISA is specific,
271 rapid and accurate for screening METH positive oral fluid sample. However, there was a
272 significant cross-reactivity with MDMA drug. Cross-reactivity tendencies in ELISA
273 technique could be regarded as a major setback since results obtained have to be further
274 confirmed using a more specific technique like GC-MS. Therefore, ELISA technique should
275 be validated for each type of drugs in different matrices.
