# Forage Potential of Alfalfa with Oats and Barley in Sole and Intercropping Systems

- 4
- 5

#### 6 ABSTRACT

7 Production of planted pastures with high energy and protein levels remains a challenge during winter 8 months for livestock. Field trials were conducted to investigate the effects of cropping systems using 9 intercropping (alfalfa + oat and alfalfa + barley) and monocropping (alfalfa, oat and barley) on plant 10 height, yield and quality characteristics. Furthermore, to study the competition experienced by legume 11 and cereals when planted in a mixture. The field trial was carried out in a randomized complete block 12 design (RCBD) with five treatments including sole oat, sole barley and sole alfalfa, alfalfa + oat 13 intercropping and alfalfa + barley intercropping and three replicates. The study was conducted at the 14 Experimental Farm of the National University of Lesotho for two growing seasons during the winter 15 seasons of 2015 and 2016. The results revealed that intercropping increased yields of forage crops 16 than monocrops. Intercropping significantly increased protein levels and reduced fibre concentrations. 17 In intercropping competition indices, land equivalent ratios (LER's) indicated yield advantages for 18 intercropping. Relative crowding coefficient (K) and aggressivity (Ac) values showed significant 19 advantages of cereal over legume indicating legume was less competitive than cereal. In summary, 20 intercropping system was more productive than respective monocrops.

#### 38 **1. INTRODUCTION**

39 Intercropping is system including two or more crop species sown in the same time and growing 40 together on the same field [1]. Intercropping of legumes together with cereals for food or forage is 41 used in many parts of the world and has shown great potential in many ways. Intercrops have 42 potential on crop productivity by reducing weed pressure, sustaining plant health and improving dry 43 matter yields [2]. Intercrops sustain fertility status of soil and the possibility of nitrogen accumulation 44 from the leguminous plants to other plants in the soil. Biological fixation of nitrogen is completed by 45 two nitrogen fixing bacteria namely free living bacteria in the soil and symbiotic relationship bacteria 46 which live in the leguminous plant roots enriching surrounding soil with usable nitrogen for cereal 47 plants [3].

48 Cereal-legume combinations are often used for forage and as cover crops. On animal husbandry, 49 legume-cereal mixtures may be interesting forage harvested for green fodder and maintenance of 50 continuity of feed supply [4]. In other studies, winter grain like rye and wheat combined with a 51 leguminous plant as cover crop. Intercrops protect soil from erosion, help improve soil tilth, and left as 52 dead mulch at the soil surface. Very often the legume provides nitrogen, while the cereal produces 53 organic matter [5]. Some research indicates that legume plants like clover fix more nitrogen into plant-54 usable form when grown with cereals such as grasses than when planted in a pure stand [6]. 55 Intercrops including legumes are known to use natural resources well and enhance forage than cereal 56 sole cropping [7].

57 However, in Southern African countries in particular, Lesotho, intercropping of legume and cereals 58 mixture for production of forage is not a common cropping system in winter season. Monocultures of 59 leguminous plants or cereal crops are rarely used for forage and do not provide satisfactory results for 60 fodder production [8]. In particular, production of forage from cereals is usually lower than that 61 required to meet satisfactory nutritional requirements for ruminant animals. Among causes of 62 declining livestock productivity in Lesotho are the deteriorating communal rangelands, low use of 63 planted forages and low quality feeds in winter and spring season. Ruminant animals often face green 64 forage scarcity during winter and spring months and thus have to survive on cereal residues of 65 previous plants including maize straw and sorghum stalk which are not rich source of digestible 66 nutrients.

Intercropping systems may contribute significantly to the winter and spring season diet of animals [9]. Other studies reported the benefits of growing leguminous plants together with cereal crops in winter months. Intercrops including alfalfa legume and cereals like oat and barley are the important winter forage for the sustenance of livestock. Studies have shown that nutritive value and yield of forage is high when produced in cereal legume mixtures [10; 11]. Cereal crops provide with sufficient amount of carbohydrate, while legumes are efficient in increasing protein and mineral content of forage which is necessary for livestock health and productivity. 74 Alfalfa (Medicago sativa L.) is herbaceous legume that has great growth productivity and good fodder 75 recovery after cutting [12]. Alfalfa has ability to add nitrogen to the soil and store energy in the root 76 crown that helps the buds in a quick re-growth which results in high yield [13]. Alfalfa is most 77 important and profitable legume used for production of fodder mainly in intercrops combinations. 78 Mixtures of alfalfa legumes with cereals forage (rye) greatly improve minerals and decrease the 79 prevalence of pasture bloat [14]. Alfalfa has ability to adapt to various environmental conditions and 80 tolerates low temperatures. It was stated that alfalfa and wheat in intercropping system in winter 81 months increased yield, improved growth, reduced weeds, made a better soil coverage and keep it 82 from erosion [15].

83 Oat plant (Avena sativa L.) is forage crop planted primarily for grain and fodder, and often grown with 84 a leguminous plant [16]. Oats form an excellent combination and produced high yields, forage quality 85 and minerals when planted along with other winter season legume crops including vetch (Vicia sativa) 86 and senji (Indian clover) [17]. Studies have shown that some intercropping systems such as vetch 87 (Vicia sativa) – oats intercropping have a great potential for improving nutritive value of forage 88 compared to sole cropping [18], whereas other intercropping systems such as berseem (Trifolium 89 alexandrinum)-oats intercropping protect soil from erosion, limit weed population and enhance forage 90 productivity [19; 20]. Oats-shaftal (Persian clover) intercropping has been shown to reduce diseases, 91 suppress weeds, and improve the nutritive (protein) value of crop compared to oats alone [21].

92 Barley plant (Hordeum vulgare L.) is a leafy forage species and produce valuable fodder for livestock. 93 Barley can be conserved in the form of hay or silage and used later when pastures become 94 unproductive [22]. In forage cropping system, barley forage has been planted in mixture with a 95 legume such as berseem (Trifolium alexandrium) and Persian clover (Trifolium resupinatum) and 96 improved fodder production [23]. Studies have shown that berseem clover and barley mixture 97 produced higher forage productivity and nutritive value than sole barley [24]. Intercropping barley with 98 vetch produced greater yields and nutritive value higher than either cereal or legume crop alone [25]. 99 In this study, the hypothesis was that cropping systems impacted forage production mainly through 100 influencing nutritive value composition and plant growth attributes. This study was therefore, 101 conducted to determine forage yield potential and nutritive value profile of alfalfa with oats and barley 102 cultivars at four growth stages in intercropping and sole cropping systems, and to study the influence 103 of intercropping system on growth rate of cereal-legume species planted in the mixtures.

115

#### 116 **2.2 Forage Management and Experimental Design**

117 The field trial comprised of alfalfa, barley and oats planted in pure stands and intercropping alfalfa legume with barley and oats plants. Seedbed was prepared with tractor disc harrow. Animal manure 118 was applied at the rate of 70kgha<sup>-1</sup> and incorporated into the soil before planting to reflect the common 119 120 practice. Forage seeds were planted after soil tillage. Seeding rates used for oat, barley and alfalfa crop were sown at rate of 80, 100 and 25 kgha<sup>-1</sup> respectively. In mixture combinations, the seed of 121 122 component forage crops was homogenised at 50:50 ratios before planting. The sole crop and 123 intercrop treatments were established in rows spaced 30 cm apart within 10m by 20m plots; the 124 intercrops of alfalfa with oats and barley were planted in alternate rows with the same row spacing 125 done with a single row drill. Alfalfa seed was inoculated with rhizobia to encourage biological nitrogen 126 fixation. The field trial was carried out in a randomized complete block design (RCBD) with five 127 treatments including sole oat, sole barley and sole alfalfa, alfalfa + oat intercropping and alfalfa + 128 barley intercropping and three replicates. Supplementary irrigation was not applied after days of 129 sowing. Rainfall and temperature recorded are presented in Table 2 during the forage crop growth 130 period.

#### 131 2.3 Forage Measurements

#### 132 **2.3.1 Plant Height**

The plant height was measured at the major growth stages (tillering, booting, flowering and ripening) using disc pasture meter by averaging nine readings recorded inside a 2m x 2m square guadrat.

#### 135 2.3.2 Forage Yield

Dry matter (DM) was measured at the major growth stages by harvesting aboveground materials within the 4m<sup>2</sup> quadrat randomly sampled in each plot using manual shears. Forage samples of biomass for alfalfa, oat and barley species from each plot were oven dried at 80°C for at least 48 h to measure the dry matter yield.

#### 140 2.3.3 Forage Quality

A second set of random samples of biomass for forage species of each plot was taken at each major growth stages to measure the forage quality; crude protein (CP), acid detergent fibre (ADF) and neutral detergent fibre (NDF) in the Department of Animal Science Laboratory. CP based on DM was calculated by multiplying the Nitrogen (N) content by 6.25 determined using Kjeldahl method [26]. NDF based on DM was measured by boiling a forage sample using neutral detergent under neutral pH conditions. ADF was measured using acid detergent under low pH condition [27].

#### 147 2.3.4 Intercropping Competition Indices

Land equivalent ratio (LER), the relative crowding coefficient (K) and the aggressivity (A) were calculated to determine the impact of competition between the legume and cereal in a mixture stands. LER shows the efficiency of intercropping compared to sole cropping for use of environmental resources. When LER is lower than one the intercropping have not improved species productivity, whereas, when LER is greater than one the intercropping improved the productivity of the intercropped species [28]. The LER was calculated according to the following equation:

154 LER = 
$$\left(\frac{Y_{LI}}{Y_L}\right) + \left(\frac{Y_{CL}}{Y_C}\right)$$

Where Y is the yield per unit area,  $Y_L$  and  $Y_C$  are the yields of legume (alfalfa) and cereal (oat or barley), respectively, as monocrops and  $Y_{LI}$  and  $Y_{CI}$  are the yields of legume (alfalfa) and cereal (oat or barley), respectively, as intercrops.

The relative crowding coefficient (K) measures the relative dominance of one species in a mixture stands. There is no competition when K is equal to one, the species is less competitive when K is lower than one and the species is more competitive in resource use when K is greater than one [29]. The K was calculated with the following equation:

162 
$$K_{L} = \frac{Y_{LI}Z_{CI}}{(Y_{L} - Y_{LI})Z_{LI}}$$

163 
$$K_{C} = \frac{Y_{CI}Z_{LI}}{(Y_{C} - Y_{CI})Z_{CI}}$$

164 Where,  $Z_{LI}$  is the sown proportion of Legume (alfalfa) in mixture stands and  $Z_{CI}$  the sown proportion of 165 cereal (oat or barley) in mixture stands.

- 166 Aggressivity measures the competition between two different plant species. Both plants are equally
- 167 competitive if A<sub>c</sub> is equal to zero. The cereal is the dominated species if A<sub>c</sub> is negative. The cereal
- 168 species is dominant if Ac is positive [29]. The aggressivity is derived from the following equation:

169 Aggressivity of Legume (alfalfa) 
$$A_{L} = \left(\frac{Y_{LI}}{Y_{L}Z_{LI}}\right) - \left(\frac{Y_{CI}}{Y_{C}Z_{CI}}\right)$$

170 Aggressivity of Cereal (oat or barley)  $A_{C} = \left(\frac{Y_{CI}}{Y_{C}Z_{CI}}\right) - \left(\frac{Y_{LI}}{Y_{L}Z_{LI}}\right)$ 

#### 171 **2.4 Statistical Methods**

Statistical Analysis System proc mixed procedure was used for data analysis [30]. Analysis of variance (ANOVA) was performed to measure the effects of intercropping and sole cropping treatments on productivity of forage. Treatment means were separated using a Fisher's protected Least Significant Difference (LSD) test and differences were considered significant at P≤0.05. Mean comparison was conducted using Duncan multiple range test.

#### 177 3. RESULTS AND DISCUSSION

#### 178 **3.1 Forage growth and yield attributes**

#### 179 3.1.1 Plant Height

180 Plant height recorded at different forage growth stages showed significant differences among 181 cropping system treatments in Table 3. In 2015, maximum plant height was attained by intercropping 182 treatments alfalfa + oat (55.7cm) and alfalfa + barley (54.5cm) compared to monoculture treatments 183 oats alone (52.5 cm), barley alone (51.7cm) and the lowest by alfalfa alone (33.9cm). In 2016, plant 184 height was significantly higher in intercropping treatments than in monoculture treatments. Plant 185 height is a major parameter of crop productivity that maximizes the use of the climatic and surface 186 environmental resources available, especially light, carbon dioxide, water and nutrients, allowing the 187 production of maximum crop yield [31]. From the results, it appeared that the height character in 188 intercropping is mainly higher than monoculture which could be the result of efficient utilization of 189 climatic and environmental resources and minimum competition among the plants of different species; 190 legume and cereal. There is possibility that the alfalfa legume may have produced and shared 191 biologically fixed nitrogen with its oat and barley cereals. These results are similar with the findings of 192 other studies, who reported the highest plant height in mixture stand than pure stand [7; 32; 4].

198 d – Days after emergence. Means in the same column followed by different letters differ significantly 199 at  $P \le 0.05$ .

#### 200 3.1.2 Forage Yield

201 Forage dry matter yield recorded at different growth stages of the monoculture and intercropping 202 system is presented in Table 4. There were significant differences among the forage dry matter yield 203 at different plant growth stages for the two consecutive years. In 2015, alfalfa + oat produced the areatest forage yield at 39.2 tha-1 followed by alfalfa + barley at 37.8 tha-1, sole oat at 36.3 tha-1, sole 204 barley at 34.9 tha-1 and sole alfalfa the lowest at 32.8 tha-1. In 2016, forage dry matter was 205 206 significantly higher in alfalfa + oat and alfalfa + barley than sole oat, sole barley and sole alfalfa. Sole oat, sole barley and sole alfalfa had forage dry matter yield decreased from 36.3 tha<sup>-1</sup>, 34.9 tha<sup>-1</sup> and 207 208 32.8 tha<sup>-1</sup> in 2014 to 35.8 tha<sup>-1</sup>, 33.7 tha<sup>-1</sup> and 31.6 tha<sup>-1</sup> respectively in 2016, this could be partly due 209 to their continuous planting on the same area for two consecutive years. Forage intercropping 210 systems showed significant advantages in dry matter yield over monocultures. This effect is likely 211 related to niche differentiation in intercropping in spatial resources use; leaves for light and roots for 212 water, which made intercrops able to utilize natural resources at different times during different growth 213 stages. Intercrops were also effective as suppressing weeds. There was possibility that the alfalfa 214 legume may have released the fixed nitrogen to oat and barley cereal counterpart. Leguminous plant 215 in mixtures of cereal + legume usually has direct benefits of nitrogen fixation in root nodules and 216 contributed to soil fertility which was used by companion as well as subsequent crops [33]. Previous 217 studies reported a similar response of more forage yield produced from cereal-legume mixtures than 218 sole cereal/legume [34; 35; 36].

## Table 4. Forage yields of alfalfa, oat and barley monocultures and intercrops of alfalfa with oat and barley at different plant growth stages during two winter seasons 2015 and 2016

Cropping	Plant growth stages (tha <sup>-1</sup> )

<sup>222</sup> at P≤0.05.

#### 223 3.2 Forage Quality

#### 224 3.2.1 Crude Protein (CP)

225 Crude protein of forage mixtures and pure stands at four growth stages is presented in Table 5. 226 Forage crude protein data indicated that there was significant difference among treatments for two 227 consecutive years. In 2015, maximum crude protein content (21.1 gkg<sup>-1</sup>) was obtained from alfalfa + 228 oats, followed by alfalfa + barley, sole alfalfa, sole oats and the lowest by sole barley. In 2016, forage 229 crude protein was significantly higher in alfalfa + oat, alfalfa + barley, sole alfalfa than in sole oat and 230 sole barley. Crude protein (CP) is often regarded to be the most important parameter of forage quality 231 [37; 4]. The results showed that alfalfa + oat, alfalfa + barley, sole alfalfa forage produced higher 232 crude protein content than their respective cereal counter parts; sole oats and sole barley, which 233 could be the result of efficient utilization of light, atmospheric nitrogen, moisture and nutrients. 234 Legumes tend to have higher crude protein levels than cereal crops through biological fixation of 235 nitrogen, thus an overall improvement in crude protein is to be expected when legumes are 236 intercropped with cereals. Crude protein improvement in legume-cereal intercropping has been 237 reported by several studies, who reported a higher crude protein content relative to that of sole 238 cereals [5; 38; 39].

## 239Table 5. Crude protein (CP) in forage yield of alfalfa, oat and barley monocultures and240intercrops of alfalfa with oat and barley at different plant growth stages over a two241year period

Cropping	Plant growth stages (gkg <sup>-1</sup> )

d – Days after emergence. Means in the same column with different letters are significantly different ( $P\leq 0.05$ ).

#### 244 3.2.2 Acid Detergent Fibre (ADF)

245 Acid detergent fibre (ADF) recorded at different growth stages of two cropping systems; monoculture 246 and intercropping is given in Table 6. ADF data revealed that there was significant difference among 247 treatments for two consecutive years. In 2015, the highest ADF (32.1) was obtained from sole barley 248 followed by sole oat (30.6) and sole alfalfa (30.2) while lowest ADF (28.6 and 27.4 respectively) was 249 recorded with alfalfa + barley and alfalfa + oats intercropping system. In 2016, ADF values were also 250 highest in barley, oat and alfalfa monocultures (33.5, 32.4 and 31.2 respectively) and lowest in 251 intercrops of alfalfa with barley and oat (28.9 and 27.7 respectively). Acid detergent fibre (ADF) is 252 important criteria for evaluating forage quality, represents the digestible energy that means as the 253 ADF level increases, digestible energy levels decrease [36]. From the results of the study legumecereal intercrops have low ADF values whereas monocultures have high values. This could be partly due to efficient utilization of natural resources; light, atmospheric nitrogen, carbon dioxide, moisture and nutrients among the plants of different species legumes and cereals during different growth stages. The incorporation of legume with cereal could be of paramount importance to the low ADF of the forage mixture and subsequent soil health. These results are in line with the findings of other studies, who reported that combined cereal–legume forage had lower ADF concentration than sole cereal/legume [40; 10; 6].

261Table 6. Acid detergent fibre (ADF) in forage yield of alfalfa, oat and barley monocultures and262intercrops of alfalfa with oat and barley at different plant growth stages over a two263year period

#### 266 3.2.3 Neutral Detergent Fibre (NDF)

267 Neutral detergent fibre (NDF) data regarding alfalfa, oat and barley monocultures and intercrops of 268 alfalfa with oat and barley at four growth stages are presented in Table 7. NDF recorded at different 269 plant growth stages for two consecutive years showed significant differences among the cropping 270 system treatments. In 2015, mean maximum NDF was recorded in sole barley (51.4) followed by sole 271 oat (51.2), sole alfalfa (48.1) and the lowest by alfalfa + oat and alfalfa + barley (45.1 and 44.4 272 respectively). In 2016, maximum NDF was also noted in sole barley (51.7) followed by sole oat (50.9), 273 sole alfalfa (48.5) and the lowest in alfalfa + oat (46.1) and alfalfa + barley (45.6) intercrops. NDF 274 concentration is a major component of forage quality and negatively correlated with dry matter intake, 275 which means as NDF in the forage increases, animals will consume less forage [36]. From the results, 276 it appears that NDF values are lower in cereal legume intercrops and higher in sole cropping. The 277 lower NDF of cereal legume intercropping was probably the efficient utilization of natural resources 278 and minimum competition among the plants of different species during different growth stages. The 279 results of this study are similar with previous studies, which investigated legume cereal mixtures and 280 recorded the highest NDF in sole cropping and lowest in intercropping systems [41; 11; 2].

#### 289 3.3 Intercropping competition indices

#### 290 3.3.1 Land Equivalent Ratio (LER)

291 LER's values were calculated for intercropping treatments in two growing seasons 2015 and 2016 to 292 determine any advantage to be realized from the intercropping and presented in Table 8. All 293 intercrops showed LER greater than one. The maximum LER values were obtained from the alfalfa + 294 oat intercropping system followed by alfalfa + barley. With the values of LER higher than one from the 295 results, this could infer that the intercropping provided significant yield advantage over monocrops. 296 LER ranged from 1.05 to 1.11 in 2015 and 1.16 to 1.24 in 2016. Therefore, 5% to 11% in 2015 and 297 16% to 24% more land should be used in monocropping in order to obtain the same yield of 298 intercropping, which indicated the advantage of the intercrops over monocrops in terms of the use of 299 water, nutrients, carbon dioxide and light for plant growth. It was found that LER greater than one was 300 primarily due to the nutrient cycling and increase in nitrogen content [42].

#### Table 8. Land equivalent ratio for intercrops of alfalfa with oat and barley in two consecutive growing seasons (2015, 2016)

	Land Equivale	nt Ratio (LER)	2015	Land Equivalent Ratio (LER) 2016			
Intercropping	LER Legume	LER <sub>Cereal</sub>	LER Total	LER Legume	LER <sub>Cereal</sub>	LER <sub>Total</sub>	
Alfalfa + Oat	0.77	0.34	1.11	0.85	0.39	1.24	
Alfalfa + Barley	0.74	0.31	1.05	0.81	0.35	1.16	

303

#### 304 3.3.2 Relative Crowding Coefficient (K)

Relative crowding coefficient's values were calculated for intercropping treatments in two growing season 2015 and 2016 to determine competition experienced by legume (alfalfa) and cereals (oat or barley) when grown in a mixture and presented in Table 9. Relative crowding coefficient values were above one in 2015 and 2016 growing season for alfalfa + oat and alfalfa + barley mixtures. The K values of cereal were higher than K values of legume in intercropping system. From the results of the study, it appears that cereal forage was the dominant species probably due to the efficient utilization of environmental resources. These findings are in agreement with previous studies where there were

- 312 low relative crowding coefficient's values of the legume when the cereal was more competitive than
- 313 the legume [43; 44].

#### Table 9. Relative crowding coefficient for intercrops of alfalfa with oat and barley in two consecutive growing seasons (2015, 2016)

Intercropping		ng Coefficient (K) )15	Relative Crowding Coefficient (K) 2016		
	K Legume	K <sub>Cereal</sub>	K Legume	K <sub>Cereal</sub>	
Alfalfa + Oat	1.22	1.42	1.45	1.75	
Alfalfa + Barley	1.29	1.38	1.55	1.67	

316

#### 317 **3.3.3 Aggressivity (A**<sub>c</sub>)

318 Aggressivity values were calculated for intercropping treatments in two consecutive growing seasons 319 2015 and 2016 to determine the competitive relationship between legume and cereal in a mixture 320 (Table 10). Aggressivity has similar trend as relative crowding coefficient. Cereal was the dominant 321 species (A<sub>c</sub> positive) in the alfalfa + oat and alfalfa + barley mixtures in 2015 and 2016 growing 322 season. Considering all aggressivity values cereal showed significant advantages in aggressivity over 323 legume. Cereal aggressivity values were positive while such values for legume forage were negative. 324 This effect is likely related to spatial resource use; light, water and nutrients which made cereals able 325 to be dominant species as measured by the positive value of aggressivity. Similar results were 326 recorded by other researchers, who reported that in other intercrops (pea and barley, soya bean and 327 palisade grass) the cereal values of the above indices were greater than for legume, indicating that 328 cereal was more competitive than legume [45; 46]. Similarly, greater competitive ability of sorghum 329 and barley to exploit resources in association with chickpea and faba bean has been reported by 330 other studies [47; 48].

### Table 10. Aggressivity for intercrops of alfalfa with oat and barley in two consecutive growing seasons (2015, 2016)

	Aggressiv	ity (A) 2015	Aggressivity (A) 2016		
Intercropping	A <sub>Legume</sub>	A <sub>Cereal</sub>	A <sub>Legume</sub>	A <sub>Cereal</sub>	
Alfalfa + Oat	- 0.28	0.28	- 0.41	0.41	
Alfalfa + Barley	- 0.21	0.21	- 0.35	0.35	

333

#### 334 4. CONCLUSIONS

335	On the basis of results obtained in this study, intercropping of legume (alfalfa) with cereals (oat and
336	barley) showed many benefits. Intercropping systems significantly increased plant height and forage
337	yield compared with their respective monocrops. Legume-cereal intercrops improved forage quality in
338	terms of crude protein yield (CP), acid detergent fibre (ADF) and neutral detergent fibre (NDF)
339	concentrations than either forage species grown alone. Results obtained from intercropping
340	competition indices indicated a superior advantage of legume-cereal mixtures because of better land
341	use efficiency expressed as LER. Considering relative crowding coefficient (K) and aggressivity ( $A_c$ )
342	values, cereal showed significant advantages over legume. The results of the study show that with

alfalfa + oat and alfalfa + barley, it possible to produce greater forage yield and quality. Since there is
little information in literature on forage competition indices regarding intercropping systems, the
results from this study may start to fill this gap. If the primary interest of the farmer is forage
production, oat or barley forage should be grown with alfalfa forage.
