Forage Potential of Alfalfa with Oats and Barley in Intercropping System

- 4
- 5

6 ABSTRACT

7 Production of cultivated pastures with high energy and protein levels remains a challenge during 8 winter months for livestock. Field trials were conducted to investigate the effects of cropping systems 9 using intercropping (alfalfa + oat and alfalfa + barley) and monocropping (alfalfa, oat and barley) on 10 plant height, yield and quality characteristics. Furthermore, to study the competition experienced by 11 legume and cereals when planted in a mixture. The field trial was carried out in a randomized 12 complete block design with five treatments including sole oat, sole barley and sole alfalfa, alfalfa + oat 13 intercropping and alfalfa + barley intercropping and three replicates. The study was conducted at the 14 Experimental Farm of the National University of Lesotho for two growing seasons (2015 and 2016). 15 The results revealed that intercropping increased yields of forage crops in comparison to monocrops. 16 Intercropping significantly increased protein levels and reduced fibre concentrations. In intercropping 17 competition indices, land equivalent ratios indicated yield advantages for intercropping. Relative 18 crowding coefficient and aggressivity values showed significant advantages of cereal over legume. 19 So, intercropping system was more productive than respective monocrops.

38 **1. INTRODUCTION**

39 Intercropping is system including two or more species sown in the same time and growing together on 40 the same field [1]. Intercropping of legumes together with cerealsfor food or forage is used in many 41 parts of the world and has shown great potential in many ways.Intercropshave potential on crop 42 productivity by reducing weed pressure, sustaining plant healthand improving dry matter yields [2]. 43 Besides that sustain fertility status of soil and the possibility of nitrogen accumulation from the 44 leguminous plants to other plants in the soil. Biological fixation of nitrogen is completed by two 45 nitrogen fixing bacteria namely free living bacteria in the soil and symbiotic relationship bacteria which 46 live in the leguminous plant rootsenriching surrounding soil with usable nitrogen for cereal plants [3].

47 Cereal – legume combinations are often used for forage and as cover crops. On animal husbandry, 48 legume - cereal mixtures may be interesting forage harvested for green forage andmaintenance of 49 continuity of feed supply [4]. Inother studies, winter grain like rye and wheat combined with a 50 leguminous plant as cover crop. Intercrops protect soil from erosion, help improve soil tilth, and left as 51 dead cover at the soil surface. Very often the legume provides nitrogen, while the cereal produces 52 organic matter [5]. Some research indicates that legume plants like clover fix more nitrogen into plant 53 - usable form when grown with cereals such as grasses than when planted in a pure stand [6]. 54 Intercrops including legumes are known to use natural resources well and enhance forage than cereal 55 sole cropping [7].

56 However, in Southern African countries in particular, Lesotho, intercropping of legume and cereals 57 mixture for production of forage is not a common cropping system in winter season. Monocultures of 58 leguminous plants or cereal crops are rarely used for forage and do not provide satisfactory results for 59 forage production [8]. In particular, production of forage from cereals is usually lower than that 60 required to meet satisfactory nutritional requirements for ruminant animals. Among causes of 61 declining livestock productivity in Lesotho are the deteriorating communal rangelands, low use of 62 planted forages and low quality feeds in winter and spring season. Ruminant animals often face green 63 forage scarcity during winter and spring months and thus have to survive on cereal residues of 64 previous plants including maize straw and sorghum stalk which are not rich source of digestible 65 nutrients [8].

Intercropping systems may contribute significantly to the winter and spring season diet of animals [9]. Other studies reported the benefits of growing leguminous plants together with cereal crops in winter months. Intercrops including alfalfa legume and cereals like oat and barley are the important winter forage for the sustenance of livestock [10; 11]. Studies have shown that nutritive value and yield of forage is high when produced in cereal legume mixtures [10; 11]. Cereal crops provide with sufficient amount of carbohydrate, while legumes are efficient in increasing protein and mineral content of forage which is necessary for livestock health and productivity.

Alfalfa (*Medicago sativa* L.) is herbaceous legume that has great growth productivity and good forage
 recovery after cutting [12]. Alfalfa has ability to add nitrogen to the soil and store energy in the root

crown that helps the buds in a quick re-growth which results in high yield [13]. It is most important and profitable legume used for production of forage mainly in intercrops combinations. Mixtures of alfalfa legumes with cereals forage (rye) greatly improve minerals and decrease the prevalence of pasture toxicity [14]. Alfalfa has ability to adapt to various environmental conditions and tolerates low temperatures. It was stated that alfalfa and wheat in intercropping system in winter months increased yield, improved growth, reduced weeds, made a better soil coverage and keep it from erosion [15].

81 Oat plant (Avena sativa L.) is forage crop planted primarily for grain and forage, and often grown with 82 a leguminous plant [16]. Oats form an excellent combination and produced high yields, forage quality 83 and minerals when planted along with other winter season legume crops including vetch (Vicia sativa) 84 and senji (Indian clover) [17]. Studies have shown that some intercropping systems such as vetch 85 (Vicia sativa L.) - oats intercropping have a great potential for improving nutritive value of forage 86 compared to sole cropping [18], whereas other intercropping systems such as berseem (Trifolium 87 alexandrinum) - oats intercropping protect soil from erosion, limit weed population and enhance 88 forage productivity [19: 20]. Oats - shaftal (Persian clover) intercropping has been shown to reduce 89 diseases, suppress weeds, and improve the nutritive (protein) value of crop compared to oats alone 90 [21].

Barley plant (*Hordeum vulgare* L.) is a leafy forage species and produce valuable forage for livestock. Barley can be conserved in the form of hay or silage and used later when pastures become unproductive [22]. In forage cropping system, barley forage has been planted in mixture with a legume such as berseem (*Trifolium alexandrium*) and Persian clover (*Trifolium resupinatum*) and improved forage production [23]. Studies have shown that berseem clover and barley mixture produced higher forage productivity and nutritive value than sole barley [24]. Intercropping barley with vetch produced greater yields and nutritive value higher than either cereal or legume crop alone [25].

98 In this study, the hypothesis was that cropping systems impacted forage production mainly through 99 influencing nutritive value composition and plant growth attributes. This study was therefore, 100 conducted to determine forage yield potential and nutritive value of alfalfa with oat and barley at four 101 growth stages in intercropping and sole cropping systems, and to study the influence of intercropping 102 system on growth rate of cereal–legume species planted in the mixtures.

103 2. MATERIALS AND METHODS

104 2.1 Site Description

The study was conducted at the Experimental Farm of the National University of Lesotho (29°45'S; 27°72'E) for two growing seasons during the winter seasons of 2015 and 2016. The field trial was established on a well – drained sandy clay loam soil with medium to coarse textured whose characteristics are presented on Table 1. Weather data during the experimental period for two growing seasons is given in Table 2.

114

115 2.2 Forage Management and Experimental Design

116 The field trial comprised of alfalfa, barley and oats planted in pure stands and intercropping alfalfa 117 with barley and oats. Seedbed was prepared with tractor disc harrow. Animal manure was applied at the rate of 70 kgha⁻¹ in accordance with soil properties, in particular N content and incorporated into 118 119 the soil before planting to reflect the common practice. Seeding rates used for oat, barley and alfalfa 120 crop were sown at rate of 80, 100 and 25 kgha⁻¹ respectively. In mixture combinations, the seed of 121 component forage crops was homogenised at 50:50 ratios before planting. The sole crop and 122 intercrop treatments were established in rows spaced 20 cm apart within 10m by 20m plots; the 123 intercrops of alfalfa with oats and barley were planted in alternate rows with the same row spacing 124 done with a single row drill. Alfalfa seed was inoculated with rhizobia to stimulate biological nitrogen 125 fixation. The field trial was carried out in a randomized complete block design (RCBD) with five 126 treatments including sole oat, sole barley and sole alfalfa, alfalfa + oat intercropping and alfalfa + 127 barley intercropping and three replicates and whole experiment was conducted in rain fed conditions. 128 Rainfall and temperature recorded are presented in Table 2 during the forage crop growth period.

129 2.3 **Forage Measurements**

130 2.3.1 **Plant Height**

131 The plant height was measured at the major growth stages (tillering, jointing, flowering and ripening) 132

using disc pasture meter by averaging nine readings recorded inside a 2m x 2m square quadrat.

133 2.3.2 Dry Matter Yield

Green forage yield was measured at the major growth stages by harvesting aboveground biomass within the 4m² quadrat randomly sampled in each plot using manual shears. Forage samples from each plot were oven dried at 80°C for at least 48 h to measure the dry matter yield.

137 2.3.3 Intercropping Competition Indices

Land equivalent ratio (LER), the relative crowding coefficient (K) and the aggressivity (A) were calculated to determine the impact of competition between the legume and cereal in a mixture stands. LER shows the efficiency of intercropping compared to sole cropping for useof environmental resources. When LER is higher than one the intercropping improved the productivity of the intercropped species [28]. The LER was calculated according to the following equation:

$$\mathsf{LER} = \left(\frac{\mathsf{Y}_{\mathsf{LI}}}{\mathsf{Y}_{\mathsf{L}}}\right) + \left(\frac{\mathsf{Y}_{\mathsf{CL}}}{\mathsf{Y}_{\mathsf{C}}}\right)$$

Where Y is the yield per unit area, Y_L and Y_C are the yields of legume (alfalfa) and cereal (oat or barley), respectively, as monocrops and Y_{LI} and Y_{CI} are the yields of legume (alfalfa) and cereal (oat or barley), respectively, as intercrops.

The relative crowding coefficient (K) measures the relative dominance of one species in a mixture stands [29]. There is no competition when K is equal to one, the species is less competitive when K is lower than one and the species is more competitive in resource use when K is greater than one [29]. The K was calculated with the following equation:

$$K_{L} = \frac{Y_{LI}Z_{CI}}{(Y_{L} - Y_{LI})Z_{LI}}$$
$$K_{C} = \frac{Y_{CI}Z_{LI}}{(Y_{C} - Y_{CI})Z_{CI}}$$

Where, Z_{LI} is the sown proportion of Legume (alfalfa) in mixture stands and Z_{CI} the sown proportion of cereal (oat or barley) in mixture stands.

Aggressivity measures the competition between two different plant species [29]. Both plants are equally competitive if A_c is equal to zero. The cereal is the dominated species if A_c is negative. The cereal species is dominant if A_c is positive [29]. The aggressivity is derived from the following equation:

Aggressivity of Legume (alfalfa)
$$A_L = \left(\frac{Y_{LI}}{Y_L Z_{LI}}\right) - \left(\frac{Y_{CI}}{Y_C Z_{CI}}\right)$$

Aggressivity of Cereal (oat or barley) $A_C = \left(\frac{Y_{CI}}{Y_C Z_{CI}}\right) - \left(\frac{Y_{LI}}{Y_L Z_{LI}}\right)$

157 2.3.4 Nutritive Value (gkg-1)

A second set of random samples of biomass for forage species of each plot was taken at each major growth stages to measure the forage quality; crude protein (CP), acid detergent fibre (ADF) and neutral detergent fibre (NDF) in the Department of Animal Science Laboratory. CP based on DM was calculated by multiplying the Nitrogen (N) content by 6.25 determined using Kjeldahl method [26]. NDF based on DM was measured by boiling a forage sample using neutral detergent under neutral pH conditions. ADF was measured using acid detergent under low pH condition [27].

164 2.4 Statistical Methods

Statistical Analysis System proc mixed procedure was used for data analysis [30]. Analysis of variance (ANOVA) was performed to measure the effects of intercropping and sole cropping treatments on productivity of forage. Treatment means were separated using a Fisher's protected Least Significant Difference (LSD) test and differences were considered significant at $P \le 0.05$. Mean comparison was conducted using Duncan multiple range test.

170 3. RESULTS AND DISCUSSION

171 **3.1 Forage growth and yield attributes**

172 3.1.1 Plant Height

173 Plant height recorded at different forage growth stages showed significant differences among 174 cropping system treatments in Table 3. At tillering, maximum plant height was obtained by 175 intercropping treatments alfalfa + oat and alfalfa + barley and monoculture treatments oats alone, 176 barley alone and the lowest by alfalfa alone during two growing seasons 2015 and 2016. Cropping 177 system effect on plant height started to appear at jointing to ripening stages where maximum plant 178 height was obtained by intercropping treatments alfalfa + oat and alfalfa + barley compared to 179 monoculture treatments oats alone barley alone and the lowest by alfalfa alone during two growing 180 seasons 2015 and 2016. Plant height is a major parameter of crop productivity that maximizes the 181 use of the climatic and surface environmental resources available, especially light, carbon dioxide, 182 water and nutrients, allowing the production of maximum crop yield [31]. From the results, it appeared 183 that the height character in intercropping is mainly higher than monoculture which could be the result 184 of efficient utilization of weather and environmental resources and minimum competition among the 185 plants of different species; legume and cereal. There is possibility that the alfalfa legume may have 186 produced and shared biologically fixed nitrogen with its oat and barley cereals. These results are 187 similar with the findings of other studies, who reported the highest plant height in mixture stand than 188 pure stand [7; 32; 4].

189

3.1.2 Dry Matter Yield 195

196 Forage dry matter yield recorded at different growth stages of the monoculture and intercropping 197 system is presented in Table 4. There were significant differences among the forage dry matter yield 198 at different plant growth stages for the two consecutive years. Intercropping advantage compared to 199 monoculture started to emerge at jointing and lasted until ripening stage where forage dry matter was 200 significantly higher in alfalfa + oat and alfalfa + barley than sole oat, sole barley and sole alfalfa in 201 2015 and 2016. Sole oat, sole barley and sole alfalfa had forage dry matter yield decreased from 40.3 tha⁻¹, 46.2 tha⁻¹ and 45.7 tha⁻¹ in 2015 to 36.1 tha⁻¹, 44.9 tha⁻¹ and 42.1 tha⁻¹ respectively in 2016 at 202 203 flowering stage, and from 41.7 tha⁻¹, 48.9 tha⁻¹ and 46.2 tha⁻¹ in 2015 to 38.5 tha⁻¹, 45.1 tha⁻¹ and 42.4 204 tha⁻¹ respectively in 2016 at ripening stage, this could be partly due to their continuous planting on the 205 same area for two consecutive years. Forage intercropping systems showed significant advantages in 206 dry matter yield over monocultures. This effect is likely related to niche differentiation in intercropping 207 in spatial resources use; leaves for light and roots for water, which made intercrops able to utilize 208 natural resources at different times during different growth stages. Intercrops were also effective as 209 suppressing weeds [33]. There was possibility that the alfalfa legume may have released the fixed 210 nitrogen to oat and barley cereal counterpart. Leguminous plant in mixtures of cereal + legume 211 usually has direct benefits of nitrogen fixation in root nodules and contributed to soil fertility which was 212 used by companion as well as subsequent crops [33]. Previous studies reported a similar response of 213 more forage yield produced from cereal - legume mixtures than sole cereal/legume [34; 35; 36].

214 Table 4. Forage yields of alfalfa, oat and barley monocultures and intercrops of alfalfa with oat 215 and barley at different plant growth stages during two winter seasons 2015 and 2016

Cropping	Plant growth stages (tha ⁻¹)									
systems	Tillering (30d)		Jointing (50d)		Flowering (90d)		Ripening (110			
	2015	2016	2015	2016	2015	2016	2015	2016		
Sole alfalfa	20.8a	22.8a	28.5b	28.8b	40.3d	36.1c	41.7c	38.5c

-

²¹⁷ at P ≤ 0.05.

218 3.2 Intercropping competition indices

219 3.2.1 Land Equivalent Ratio (LER)

220 LER's values were calculated for intercropping treatments in two growing seasons 2015 and 221 2016(Table 8). All intercrops showed LER greater than one. The maximum LER values were obtained 222 from the alfalfa + oat intercropping system followed by alfalfa + barley. With the values of LER higher 223 than one from the results, this shows that intercropping is advantageous. LER ranged from 1.05 to 224 1.11 in 2015 and 1.16 to 1.24 in 2016. Therefore, 5% to 11% in 2015 and 16% to 24% more land 225 should be used in monocropping in order to obtain the same yield of intercropping, which indicated 226 the advantage of the intercrops over monocrops in terms of the use of water, nutrients, carbon dioxide 227 and light for plant growth. It was found that LER greater than one was primarily due to the nutrient 228 cycling and increase in nitrogen content [42].

Table 5. Land equivalent ratio for intercrops of alfalfa with oat and barley in two consecutive growing seasons (2015, 2016)

	Land Equivalent Ratio (LER) 2015 Land Equivalent Ratio (LER) 2					016
Intercropping	LER Legume	LER _{Cereal}	LER Total	LER Legume	LER _{Cereal}	LER Total
Alfalfa + Oat	0.77	0.34	1.11	0.85	0.39	1.24
Alfalfa + Barley	0.74	0.31	1.05	0.81	0.35	1.16

231

232 3.2.2 Relative Crowding Coefficient (K)

233 Relative crowding coefficient's values were calculated for intercropping treatments in two growing 234 season 2015 and 2016 to determine competition experienced by legume (alfalfa) and cereals (oat or 235 barley) when grown in a mixture and presented in Table 9. Relative crowding coefficient values were 236 above one in 2015 and 2016 growing season for alfalfa + oat and alfalfa + barley mixtures. The K 237 values of cereal were higher than K values of legume in intercropping system. From the results of this 238 study, it appears that cereal forage was the dominant species probably due to the efficient utilization 239 of environmental resources. These findings are in agreement with previous studies where there were 240 low relative crowding coefficient's values of the legume when the cereal was more competitive than 241 the legume [43; 44].

242Table 6. Relative crowding coefficient for intercrops of alfalfa with oat and barley in two243consecutive growing seasons (2015, 2016)

Intercropping		ng Coefficient (K))15	Relative Crowding Coefficient (I 2016		
	K Legume	K _{Cereal}	K Legume	K _{Cereal}	
Alfalfa + Oat	1.22	1.42	1.45	1.75	
Alfalfa + Barley	1.29	1.38	1.55	1.67	

244

245 **3.2.3 Aggressivity (A**_c)

Aggressivity values for intercropping treatments in two consecutive growing seasons 2015 and 2016 were presented in Table 10. Aggressivity has similar trend as relative crowding coefficient. Cereal 248 was the dominant species (A_c positive) in the alfalfa + oat and alfalfa + barley mixtures in 2015 and 249 2016 growing season. Considering all aggressivity values cereal showed significant advantages in 250 aggressivity over legume. Cereal aggressivity values were positive while such values for legume 251 forage were negative. This effect is likely related to spatial resource use; light, water and nutrients 252 which made cereals able to be dominant speciesas measured by the positive value of aggressivity. 253 Similar results were recorded by other researchers, who reported that in other intercrops (pea and 254 barley, soya bean and palisade grass) the cereal values of the above indices were greater than for 255 legume, indicating that cereal was more competitive than legume [45; 46]. Similarly, greater 256 competitive ability of sorghum and barley to exploit resources in association with chickpea and faba 257 bean has been reported by other studies [47; 48].

Table 7. Aggressivity for intercrops of alfalfa with oat and barley in two consecutive growing seasons (2015, 2016)

	Aggressiv	ity (A) 2015	Aggressivity (A) 2016			
Intercropping	A _{Legume}	A _{Cereal}	A _{Legume}	A _{Cereal}		
Alfalfa + Oat	- 0.28	0.28	- 0.41	0.41		
Alfalfa + Barley	- 0.21	0.21	- 0.35	0.35		

260 3.3 Nutritive Value

261 3.3.1 Crude Protein (CP)

262 Crude protein of forage mixtures and pure stands at four growth stages is presented in Table 5. 263 Forage crude protein data indicated that there was significant difference among treatments at different plant growth stages for two consecutive years. Forage crude protein was significantly higher in alfalfa 264 265 + oat, alfalfa + barley, sole alfalfa than in sole oat and sole barley from tillering to ripening stage in two 266 growing seasons (2015 and 2016). Forage crude protein in both intercropping and monocropping 267 gradually decreased from flowering to ripening stage in 2015 and 2016. Thus, the decrease in crude 268 protein accumulation of forage at late stage in intercropping and monocropping systems could be 269 mainly because of maturity. Crude protein (CP) is often regarded to be the most important parameter 270 of forage quality [37; 4]. The results showed that alfalfa + oat, alfalfa + barley, sole alfalfa forage 271 produced higher crude protein content than their respective cereal counter parts; sole oats and sole 272 barley, which could be the result of efficient utilization of light, atmospheric nitrogen, moisture and 273 nutrients. Legumes tend to have higher crude protein levels than cereal crops through biological 274 fixation of nitrogen, thus an overall improvement in crude protein is to be expected when legumes are 275 intercropped with cereals. Crude protein improvement in legume-cereal intercropping has been 276 reported by several studies, who reported a higher crude protein content relative to that of sole 277 cereals [5; 38; 39].

279 Table 8. Crude protein (CP) in forage yield of alfalfa, oat and barley monocultures and 280 intercrops of alfalfa with oat and barley at different plant growth stages over a two 281 year period

Cropping	Plant growth stages (gkg ⁻¹)

282

d - Days after emergence. Means in the same column with different letters are significantly different 283 (P ≤ 0.05).

284 3.3.2 Acid Detergent Fibre (ADF)

285 Acid detergent fibre (ADF) recorded at different growth stages of two cropping systems; monoculture 286 and intercropping is given in Table 6. ADF data revealed that there was significant difference among 287 treatments at different plant growth stages for two consecutive years. The highest ADF was obtained 288 from sole barley followed by sole oat and sole alfalfa while lowest ADF was recorded with alfalfa + 289 barley and alfalfa + oats intercropping system from tillering to ripening stage in two growing seasons 290 (2015 and 2016). Acid detergent fibre (ADF) is important criteria for evaluating forage quality, 291 represents the digestible energy that means as the ADF level increases, digestible energy levels 292 decrease [36]. From the results of the study legume - cereal intercrops have low ADF values whereas 293 monocultures have high values. This could be partly due to efficient utilization of natural resources; 294 light, atmospheric nitrogen, carbon dioxide, moisture and nutrients among the plants of different 295 species legumes and cereals during different growth stages. The incorporation of legume with cereal 296 could be of paramount importance to the low ADF of the forage mixture and subsequent soil health. 297 These results are in line with the findings of other studies, who reported that combined cereal -298 legume forage had lower ADF concentration than sole cereal/legume [40; 10; 6].

299 Table 9. Acid detergent fibre (ADF) in forage yield of alfalfa, oat and barley monocultures and 300 intercrops of alfalfa with oat and barley at different plant growth stages over a two 301 year period

Cropping	Plant growth stages (gkg ⁻¹)									
systems	Tillering (30d)		Jointing (50d)		Flowering (90d)		Ripening (110d)			
	2015	2016	2015	2016	2015	2016	2015	2016		
Sole alfalfa	18.1ab	20.1b	23.3ab	22.1b	37.3b	39.4b	42.2a	43.2a		
Sole oat	19.9ab	21.4b	21.6b	23.9a	39.1a	41.3ab	41.9a	42.8ab		
Sole barley	21.7a	23.1a	25.5a	24.6a	38.9a	42.8a	42.2a	43.5a		
Alfalfa + Oat	17.8b	18.6c	20.6b	21.8b	34.5c	32.8d	36.8b	37.4c		
Alfalfa + Barley	18.5ab	19.2c	22.1b	22.2b	35.8c	35.6c	37.9b	38.7c		
Standard Error (±)	0.58	0.80	1.46	0.82	1.55	1.84	0.76	1.04		

302 d – Days after emergence. Means in the same column followed by different letters differ significantly 303 at P ≤ 0.05.

305 3.3.3 Neutral Detergent Fibre (NDF)

306 Neutral detergent fibre (NDF) data regarding alfalfa, oat and barley monocultures and intercrops of 307 alfalfa with oat and barley at four growth stages are presented in Table 7. NDF recorded at different 308 plant growth stages for two consecutive years showed significant differences among the cropping 309 system treatments. Maximum NDF was recorded in sole barley, sole oat, sole alfalfa and the lowest 310 by alfalfa + oat and alfalfa + barley from tillering to ripening stage in two growing seasons (2015 and 311 2016). NDF concentration is a major component of forage quality and negatively correlated with dry 312 matter intake, which means as NDF in the forage increases, animals will consume less forage [36]. 313 From the results, it appears that NDF values are lower in cereal legume intercrops and higher in sole 314 cropping. The lower NDF of cereal legume intercropping was probably the efficient utilization of 315 natural resources and minimum competition among the plants of different species during different 316 growth stages. The results of this study are similar with previous studies, which investigated legume 317 cereal mixtures and recorded the highest NDF in sole cropping and lowest in intercropping systems 318 [41; 11; 2].

Table 10. Neutral detergent fibre (NDF) in forage yield of alfalfa, oat and barley monocultures and intercrops of alfalfa with oat and barley at different plant growth stages over a two year period

Cropping	Plant growth stages (gkg ⁻¹)									
systems	Tillering (30d)		Jointing (50d)		Flowering (90d)		Ripening (110d)			
	2015	2016	2015	2016	2015	2016	2015	2016		
Sole alfalfa	35.6ab	33.8b	40.1ab	39.8b	55.2b	57.4a	61.5b	62.9b

Alfalfa + Barley	29.2c	36.4ab	40.5ab	41.7ab	52.8c	49.3b	55.2c	55.1c		
Standard Error (±)	0.52	1.76	1.28	0.95	1.85	1.96	1.65	1.81		

322 d – Days after emergence. Means in the same column with different letters are significantly different 323 ($P \le 0.05$).

324 4. CONCLUSIONS

325 On the basis of results obtained in this study, intercropping of legume (alfalfa) with cereals (oat and 326 barley) showed many benefits. Intercropping systems significantly increased plant height and forage 327 yield compared with their respective monocrops from jointing to ripening stage in two growing 328 seasons (2015 and 2016). Results obtained from intercropping competition indices indicated a 329 superior advantage of legume-cereal mixtures because of better land use efficiency expressed as 330 LER. Considering relative crowding coefficient (K) and aggressivity (A_c) values, cereal showed 331 significant advantages over legume for two growing seasons (2015 and 2016). Legume – cereal 332 intercrops improved forage quality in terms of crude protein yield (CP), acid detergent fibre (ADF) and 333 neutral detergent fibre (NDF) concentrations than either forage species grown alone from tillering to 334 ripening stage in two growing seasons (2015 and 2016). The results of the study show that with alfalfa 335 + oat and alfalfa + barley, it is possible to produce greater forage yield and quality. Since there is little 336 information in literature on forage competition indices regarding intercropping systems, the results

- from this study may start to fill this gap. If the primary interest of the farmer is forage production, oat or
- barley forage should be grown with alfalfa forage and harvested between jointing and flowering stage.
