Original Research Article Effect of Land Uses and Physical Soil and Water Conservation Practices on Runoff and Soil Loss in Western Tigray, Ethiopia

6 ABSTRACT 7

8 A field experiment was conducted in three consecutive years (2014-2016) in western zone of 9 Tigray, Northern Ethiopia. It was conducted with the objectives of estimating the runoff and 10 soil loss of four different land uses. Area closure, grazing land, treated cultivated land and 11 untreated cultivated land were selected in a watershed. A total of 12 runoff plots with a size 12 of 15 m by 3 m were constructed in each land use type with the same slope (8.5%). About 25 13 cm height corrugated iron was constructed for each plot. A runoff collection ditch with 14 dimensions of 2 m length, 1.2 m width and 1 m depth was dug and lined with thick plastic 15 sheet at the bottom side of each runoff plots to collect runoff discharge and sediment yield. After each rainfall event runoff volume in the ditch was measured and subsequently one liter 16 17 sample was taken to laboratory from each runoff collection ditch after the runoff is mixed 18 vigorously. Samples filtered using filter paper and oven dried at 105 °C for 24 hours for sediment concentration calculation. The highest average surface runoff is 7277 m³/ha/year 19 and the corresponding soil loss 110 t/ha/year were recorded in the grazing land. The lowest 20 21 runoff (597 m³/ha/year) and lowest soil loss (2 t/ha/year) were also recorded in the area 22 closure treated with stone bund plus trench and tree plantation. Hence, the actual runoff and 23 soil losses recorded were higher in untreated cultivated land and grazing land than area 24 closure and treated cultivated land which warrant the requirement of more effective soil and 25 water conservation measures. Therefore, area closure treated with the integration of physical soil water conservation measures is the best technology for rehabilitation of degraded land. 26 27 Stone bund is also the best technology on cultivated land to conserve soil and water.

28 Keywords: Land use, runoff plots, runoff, soil loss

29 1. INTRODUCTION

30

Land use and land cover change through inappropriate agricultural practices, deforestation and high human and livestock population pressure have led to severe land degradation in the Ethiopian highlands [1]. As a result, biodiversity loss and soil erosion are the common occurrences. According to [2] and [3] land degradation, which includes the degradation of vegetation cover, soil erosion, and nutrient depletion, is a major ecological and economical problem in Ethiopia. Understanding the complexity of land-use and land-cover and their driving forces and impacts on environmental security is important for the planning of natural
resource management and associated decision making [4]. According to [5] and [6], soil
losses in the Ethiopian highlands reach 200-300 t/ha annually.

40

Performance of soil erosion control measures is location specific [7]. In recent days the idea of area development using an integrated watershed management approach has received recognition in the national development strategy. This must be done by research activities. Integrated watershed management is expected to improve the interaction between the physical, social, technological, economic and policy dimensions; interdisciplinary approach to solving problems; and the full participation of all stakeholders during problem identification, planning, implementation, monitoring, and evaluation.

49 **2. MATERIALS AND METHODS**

2.1. Description of the Study Area

- 50
- 51
- 52

The study was conducted during 2014 to 2016 at Welkait district, Western Zone of Tigray, Northern Ethiopia. It is located at the west of Mekelle the capital of the Tigray region, at 13°30' N and 37°10' E, with an elevation of 700 to 2354 massle (Figure.1). The mean annual rainfall of the area ranges from 700 to 1800 mm. Most of the rainfall is concentrated during the main rainy season which extends from June to September. The maximum temperature ranges from 17.5 to 25 °C.

61 2.2 Experimental Design

62 A model watershed of different land uses with and without soil and water conservation 63 (SWC) practices was selected. Each land use type was indicated in the model watershed. A 64 total of 12 runoff plots with a size of 15 m*3 m was formulated in each land use types with 65 the same slope (8.5%) in Cambisol soil type. About 25 cm height corrugated iron and stone 66 wall was constructed for each plot. A runoff collection ditch with dimensions of length, width and depth; 2 m, 1.2 m and 1 m respectively was dug and lined with thick plastic sheet at the 67 68 bottom side of each runoff plots to collect runoff and sediment. A plastic rain gauge was 69 installed to measure daily rainfall. After each rainfall event runoff volume in the ditch was 70 measured and subsequently 1 liter sample was taken to laboratory from each runoff collection 71 ditch after the runoff is mixed vigorously. Samples filtered using filter paper then oven dried 72 at 105 °C for 24 hours

3. RESULTS AND DISCUSSION

80 3.1 Runoff Discharge and Sediment Yield

81

82 The highest discharge (7277 m3/ha/year) and soil loss (110 t/ha/year) was recorded in the GL 83 and the lowest discharge (597 m3/ha/year) and soil loss (2 t/ha/year) was recorded in the AC 84 treated with stone-faced soil bund plus trench (Table 1a). However, treated cultivated land 85 contributed about 4 times higher soil loss compared to the treated uncultivated land (Table 86 1a). This may be due to the tillage erosion in the cropland. Desta et al. (2005) indicated mean 87 annual soil loss from the foot of the bunds due to tillage erosion. As its name indicates soil water 88 conservation structures conserve not only soil but significant amount of runoff discharge. 89 This study was done using runoff plot method which covers only 181.5 ha; so it is better to 90 do using spatial analysis method in order to cover a large area.

91 Table 1a. Average runoff discharge and sediment yield

Treatments	Runoff ($m^3 ha^{-1}$)					Soil loss (t ha ⁻¹)			
	2014	2015	2016	Average	2	2014	2015	2016	Average
Treated uncultivated	441	306	1045	597	1	.3	0.9	2.5	2
Grazing land	6708	6876	8248	7277	1	33.8	81.0	115.1	110
Treated cultivated	1234	1401	1440	1358	7	7.9	6.9	10.1	8
Untreated cultivated	5776	5931	7964	6557	1	04.8	59.3	74.2	79

95 4. CONCLUSIONS

96

97 Results clearly indicate that area closure treated with tree plantation, can be used to reduce soil loss 98 and runoff volume effectively. Further, stone-faced soil bund was almost equally effective in reducing 99 runoff, soil loss in cultivated land. These two land use management practices were significantly 100 superior to grazing land and cropland in reducing runoff and soil erosion. However, the highest soil 101 loss was recorded in the Grazing Land. A positive linear correlation was observed between runoff 102 and soil loss.

5. RECOMMENDATIONS

- Area closure treated with the integration of physical soil and water conservation measures is
 the best technology for rehabilitation of degraded land
- Stone bund is also the second-best technology on cultivated land to conserve soil and moisture
- This study was done using runoff plot method which covers only 181.5 ha, so other
 estimation/evaluation methods such as spatial analysis or other models might cover a large
 area
