# An Appraisal of Software Requirement Prioritization Techniques

## ABSTRACT

## 4 5

In recent times, there is a paradigm shift from the use of paper based systems to the use of software systems in all spheres of life. However, the development of high quality, cost effective and useable software systems is a major challenge. One of the major obstacles confronting the successful implementation of software systems is the inability to implement all stakeholders' requirements in software development projects. This constraint is usually due to limited human resources, budget and time. Thus, most software systems have failed. It therefore becomes pertinent to prioritize software requirements. Requirement prioritization involves the selection of requirements that are considered more important from an accumulated list of stakeholders' requirements. There are two techniques that are used for categorizing software requirements. These techniques include the requirement prioritization methods and the negotiation method. Requirement prioritization methods are based on different scales which include nominal scale, ordinal scale and ratio scale. The accuracy of these methods however is a challenge especially when prioritizing large number of requirements.

**Aims:** Hence, this paper reviews different techniques for prioritizing requirements by highlighting their strengths and weaknesses. Techniques such as binary search tree, AHP, hierarchy AHP, priority group/Numerical Analysis, bubble sort, MoSoW, simple ranking and Planning Game were analyzed and compared in this study.

Methodology: The study is based on previous literature on requirement prioritization.

**Results:** The study showed that numerical assignment and simple ranking methods require less time in the prioritization process and they also have low scalability and reliability. The study also showed that the analytic hierarchy process requires more time for requirement prioritization; it is reliable but it is not scalable. The study also revealed that it is difficult to prioritize requirement with the existing prioritization techniques when multiple stakeholders are involved.

**Conclusion:** The study suggests that future researches should be based on the design of a requirement prioritization technique that will have the ability to accommodate large stakeholders and requirements.

## 1. INTRODUCTION (ARIAL, BOLD, 11 FONT, LEFT ALIGNED, CAPS)

13 The use of software systems is increasingly becoming an integral part of all spheres of lives such as 14 banking system, educational system and the healthcare system. For instance, in 2009, President 15 George Bush set the goal of providing every American citizen with the ability to have Electronic Health Records (EHRs) by 2014 [1]. Furthermore, President Barack H. Obama signed into law the American 16 17 Recovery and Reinvestment Act, which reserves \$17 billion exclusively for the development of EHR 18 systems [2]. This is because software systems play key roles in healthcare by reducing medical errors and cost, facilitating interoperability amongst healthcare providers and patients as well as providing 19 20 facilities for remainders and appointment scheduling. However, as the use of software system 21 becomes prevalent in all sectors of life so also is the volume of requirements derived from its 22 stakeholders. Consequently, the requirements elicited from stakeholders are usually competing, 23 conflicting and ambiguous. Hence, research has shown that about 70% of software systems have 24 failed or have not satisfied the end users [3]. Consequently, people avoid the use of software systems 25 even after investing much expense and time. One of the major factors responsible for this challenge is 26 the impossibility of implementing all stakeholders' requirements into the software system due to 27 limited human resources, budget and time. Hence, there is a need to prioritize software requirements. 28 Requirements prioritization according to Karlsson and Ryan [4] is the process of selecting the 29 appropriate set of requirements from a multitude of competing and conflicting expectations elicited from various stakeholders involved in a software development project. Conversely, Firesmith [5] 30 31 defines requirements prioritization as the process of determining the implementation order of the

1

2

3

32 requirements for implementing a software system. The benefits of requirement prioritization are 33 numerous. For instance, Karlsson and Ryan [4], pointed out that requirement prioritization reduces software development cost and time by 40%. In addition, requirement prioritization helps to identify 34 the most valuable requirements from a set of voluminous and ambiguous requirements as well as 35 36 reduce software failure. Berander and Andrews [6] emphasized that requirement prioritization resolve 37 disagreements or disparities amongst stakeholders. Hence, requirement prioritization improves the 38 quality of a software release. Requirement prioritization can therefore be said to be one of the most 39 crucial stages in software development process.

40 There are two techniques that are used for categorizing software requirements. These techniques 41 include the requirement prioritization methods and the negotiation method. Requirement prioritization 42 methods are categorized on three basic scales which include nominal scale, ordinal scale and ratio 43 scale [7]. In nominal scale, requirements are assigned to different priority groups, whereby all 44 requirements in one priority group are of equal priority. The ordinal scale method usually results in an 45 ordered list of requirements while the ratio scale method provides the relative difference between 46 requirements. Requirements negotiation focuses on the assignment of priorities to requirements 47 through the consensus of the stakeholders. Typical example of requirement negotiation is winwin 48 method. Each of this technique is characterized by different challenges which include reliability problems, problems of consistency check, reliability with multiple stakeholders and difficulty when 49 50 prioritizing large numbers of requirements [7]. Hence, it becomes difficult for stakeholders to choose 51 the right technique when prioritizing requirements. Consequently, this study examines diverse requirement prioritization techniques with the aim of assisting stakeholders to choose the right 52 requirement prioritizing technique during a software development project. 53 54

#### 55 2. OVERVIEW OF SOFTWARE REQUIREMENT

56 There is no precise definition for software requirements as different authors view software 57 requirements in different contexts. For instance, IEEE [8] defines a requirement in the following ways: 58

- a. A condition or capability needed by a user to solve a problem or achieve an objective.
- b. A condition or capability that must be met or possessed by a system or system component to satisfy a contract, standard, specification, or other formally imposed documents.
- A documented representation of a condition or capability as in (a) or (b). C.

62 Furthermore, the International Standard Organization [8] defined a requirement as a statement which 63 translates or expresses a need and its associated constraints and conditions. In addition, Saranya et al. [9] viewed software requirements as what a system is required to do along with the environment it 64 65 is intended to operate in. According to Saranya et al. [9], software requirements provide the description of a system, its behavior or functionalities, application domain information, system 66 67 constraints, specifications and attributes. Gambo et al. [10] also viewed a requirement as an expression of what a software product must do to add value for its users and an expression of the 68 limitations on the choices that developers make when implementing the software. Software 69 70 requirements may be categorized as user requirements and system requirements [11]. Maiden [12] 71 refers to a user requirement as an instruction which a user provides while a system requirement 72 expresses a desirable property of a system that leads to the achievement of at least one user 73 requirement. Requirements may also be classified as primary requirements and derived requirements. 74 The primary requirements are those requirements that are elicited directly from the stakeholders while 75 the derived requirements are those requirements that are obtained from the primary requirements. 76 Requirements according to Aggarwal and Singh [13] may also be known, unknown or undreamt. The known requirements are those that the stakeholders believe must be implemented, the unknown 77 78 requirements are those that are usually forgotten by the stakeholders because they are not urgently 79 needed while the undreamt requirements are those requirements that the stakeholders may not think 80 of due to the limitation in the domain knowledge. The requirements elicited from stakeholders may be functional or nonfunctional regardless of its category. Functional requirements (FRs) describe system 81 82 services or functions while nonfunctional requirements (NFRs) are quality requirements that stipulate 83 how well a system performs its functions. Non-functional requirements are therefore attributes that 84 the system must possess.

## 86

#### 3. REQUIREMENT PRIORITIZATION 87

88 Software is critical to the advancement of almost all areas of human endeavors. Software however is 89 more than writing programs. It consists of programs; documentation of any facet of the program and the procedures used to setup and operate the software system [13]. There have however been 90 91 serious challenges on the cost, timeliness, maintenance as well as the quality of several software

92 products. Software engineering has no doubt helped in resolving these problems by producing 93 software systems that are developed within a stipulated time and budget and are also of high quality 94 and useable. One of the most crucial activities in software engineering is requirement engineering. 95 Requirement engineering can be defined as a disciplined application of proven principles, methods, 96 tools and notations that are used to describe a proposed software intended behavior and its 97 associated constraints [13]. The processes used for requirement engineering vary widely depending 98 on the application domain, the people involved and the stakeholders involved in the software 99 development process. However, there are generic activities that are common to the requirement 100 engineering process. These activities are iterative in nature and they include requirements elicitation, requirements analysis, requirements documentation and requirements review. Requirement elicitation 101 102 is basically the process of gathering requirements by reviewing available documents, observing 103 existing systems and interacting with the stakeholders through techniques such as interviews, 104 scenarios, brainstorming, Facilitated Application Specification Technique (FAST) as well as Quality 105 Function Deployment (QFD). The requirements gathered are analyzed to identify inconsistencies, 106 contradictions, defects and omissions. This is to ensure that the requirements are correct, complete, consistent and unambiguous. Requirement prioritization is one of the major activities carried out 107 108 during requirement analysis. Requirement documentation ensures that requirements are presented in 109 a consistent formant while requirement review ensures that the quality of the SRS is improved.

110 Requirements prioritization as one of the most important activities of requirement engineering is 111 concerned with the selection of the most significant requirements from a list of voluminous 112 requirements gathered from diverse stakeholders. Requirements prioritization according to Avesani et 113 al. [14] is the process of deriving an order relation on a given set of requirements, with the ultimate 114 goal of obtaining a shared rationale for partitioning them into subsequent product releases. Hence, 115 the basic goal of requirement prioritization according to Achimugu [15] is to select the most important requirements from the set of candidate requirements as perceived by relevant stakeholders. In 116 addition, Firesmith [5] viewed requirements prioritization as the process of determining the 117 118 implementation order of the requirements that are to be implemented in a software system. 119 Requirement prioritization can therefore be said to be one of the most essential activities of software 120 engineering as it involves making critical decisions that will make the software useable, cost effective 121 and of high guality. Fig.1. shows the relationship between requirements prioritization, requirements 122 engineering and software engineering. 123

127 128

124

125

126

# Fig.1. Relationship between software engineering, requirements engineering, requirements analysis and requirements prioritization (Adapted from [7])

131

## 132 **3.1 Dimensions for Prioritizing Software Requirements**

133 There are different aspects or dimensions that are used for prioritizing requirements [16]. These 134 factors include importance, time, cost, value, penalty, risk as well as precedence.

## 135 **3.1.1 Importance**

136 Importance according to Ma [7] is a multifaceted term that denotes high market value, high quality of 137 the product, or urgency of implementation. Hence, requirements of high importance are given higher 138 priorities.

# 139 **3.1.2 Time**

- 139 <u>3.1.2 Time</u>
- 140 Time refers to the total time spent on successfully implementing a candidate requirement.
- 141 3.1.3 Risk

142 Mursu [17] defined risk in software development as a product of uncertainty associated with other 143 project risk factors and the magnitude of potential loss due to project failure. In addition, Mustafa and

- 144 Al-Bahar [18] view risk as the degree of likelihood that a project will fail to achieve its time, cost or
- 145 quality goals. The definitions of risk basically have two characteristics which are probability and loss.
- 146 Risk probability is the likelihood that a risk would occur while loss is defined as an outcome that fall

short of what is expected by the stakeholders. Boban et al. [19] identified the causes of requirement risk as lack of clear product vision, lack of agreement on product requirements, un-prioritized requirements, new applications with uncertain requirements, rapidly changing requirements, ineffective requirements, change management process and inadequate impact analysis of requirements changes. If requirements-related risk factors are not controlled, a software system that does not meet the users' expectations will be developed, the cost of maintaining and enhancing such systems may be high, and the system may be unreliable and prone to errors [20].

- 154 **3.1.4 Cost**
- 155 Cost is the amount spent on successfully implementing candidate requirements.

## 156 3.1.5 Value

157 Value is the importance attached to a set of requirements when compared to other requirements

## 158 3.1.6 Penalty

159 Penalty refers to the consequences that are faced if a requirement is not implemented.

## 160 3.1.7 Precedence

Precedence refers to the condition that requires the completion of a set of requirements before another set of requirements are implemented. Hence, requirements prioritization can be said to be aimed at selecting the most appropriate requirements from a set of candidate requirements in order to satisfy the interests, technical constraints and preferences of the stakeholders involved in the software development process [21].

Karlsson et al. [22] posit that requirement prioritizing consist of three consecutive stages which include preparation, execution and presentation stages. In the preparation stage, the stakeholders structure their requirements according to the principles of the requirement prioritization method to be used. In the execution stage, the actual requirement prioritization is done using the information provided in the preparation stage while the result of the prioritization are presented to the stakeholders involved in the software development process in the presentation phase. This process is illustrated in Fig. 2.

176

177

# 178179 Fig.2. Stages of Requirement Prioritization

180

# 181 3.3 Benefits and Challenges of Prioritizing Software Requirements

182 The advantages of requirement prioritization are numerous. Hence, different authors have highlighted 183 the benefits of requirement prioritization at various times. For instance, Kukreja [23] reported that 184 requirement prioritization facilitates users' involvement in the software development process. Hence, 185 all stakeholders involved in the system development agree on the requirements that a particular 186 software release should contain. Another benefit of requirement prioritization as viewed by Hatton [16] 187 is that requirements prioritization reduces software failure which is a major challenge in software 188 development process. This is in line with the research result of Chaos [24] which reported that only 189 32% of software development projects are delivered on time, on budget, and with the required 190 features and functions, 44% are delivered late, over budget, and/or with less than the required features and functions while 24% of software development projects are usually terminated before 191 192 completion or delivered but never used. Hence, prioritizing requirements will reduce the probability of 193 software failures. Requirement prioritization helps to manage limited resources such as cost and 194 duration of a software project by addressing high priority requirements before the consideration of low 195 priority ones. Furthermore, requirement prioritization helps in planning for software releases since not 196 all the requirements elicited from multiple stakeholders can be implemented in a single software 197 release [25]. In addition, prioritizing requirements leads to increased users' satisfaction because it 198 increases the likelihood that the stakeholders' most significant requirements are implemented and 199 delivered first [5].

In spite of the numerous benefits of requirements prioritization, there are several challenges that are associated with prioritizing requirements. One of the major factors hindering requirement prioritization is changing priorities which are usually caused by changing stakeholders and requirements. The stakeholders in a software development project may change and this might result in the change of the software requirements as well as the change in the priorities of requirements [26]. In addition, the diverse views of stakeholders make it very difficult for the system analyst to identity requirements that are of high priorities. It is also difficult to efficiently prioritize requirements in domains such as the healthcare domain with large requirements. This is because this domain is made up of diverse user communities who have different requirements and priorities that may be incompatible, conflicting or contradictory. It is also difficult to prioritize requirements when resources such as cost and time are limited. Lack of trust amongst stakeholders can also be a major challenge of requirement prioritization. This is because customers that desire to implement all software requirements might assume that the developers only desire to prioritize the requirements because of their desire to eliminate some of the more difficult or risky requirements [5].

#### 4. REQUIREMENT PRIORITIZATION TECHNIQUES

Requirement prioritization techniques can be divided into two categories. These include requirement prioritization methods and requirement negotiation approaches.

#### 4.1 Requirement Prioritization Methods

The requirement prioritization methods are based on assigning values to software requirements. There are several methods used for prioritizing requirements. These prioritization techniques can be categorized as nominal scale, ordinal scale, ratio scale, machine learning methods and hybridized techniques as shown in Fig.3 

#### 4.1.1 Nominal Scale Method

In the nominal scale method, requirements are assigned to different priority groups such that the requirements in a particular group have equal priorities. Examples of nominal scale requirements prioritization method include numerical assignment MoScoW and requirement triage. 

#### 4.1.1.1 Numerical assignment

In numerical assignment method, requirements are classified into different groups based on the levels of their priority, such that the requirements in a group are of equal priority. Typical examples of priority groups include low, medium and high [27]. Another example of a priority group include critical, standard and optional. Another approach to this method is presented by Brackett [28] who classified requirements on a scale of 1 to 5, where the numbers 1-5 indicate the following

- 1. Does not matter
- Not important
- 3. Rather important.
- 4. Very important and
- 5. Mandatory.

Finally, the average value given by all stakeholders are considered as the ranking for the requirement. The difficulty of this approach is that the requirements in each group have the same priority, which means that each requirement does not get a unique priority [29, 30]. In addition, it is difficult to determine absolute information because different stakeholders have diverse opinions which make the information obtained relative [31]. In addition, the classification of requirements into different groups might confuse the stakeholders [32, 33]

297 298 299

300

## Fig.3. Requirement Prioritization Methods (Adapted from [15])

### 301 302 *4.1.1.2 MoScoW*

303 This is another form of numerical assignment method that groups requirements into four priority 304 groups. These groups include MUST have, SHOULD have, COULD have and WONT have. 305 Requirements in each of these groups are also of equal priority. The requirements in the "Must have" group are those that must be implemented in the software before it is released while the "Should 306 307 have" group represents requirements that are also important but not necessary for delivery in the 308 current software release. In addition, the requirements in the "Could have" group are desirable but not 309 necessary, and the requirements in this group will only be implemented if time and resources are abundant. The "Won't have" group contains requirements that are of low priority and are not 310 appropriate for the software release. The disadvantage of the MoSCoW prioritization technique is 311 that requirements are ambiguous when it comes to the "Wont have" group as it does not specify when 312 313 the requirements in this group would be implemented.

## 315 4.1.2.3 Top-Ten Requirement

316 In the top-ten requirements approach, the stakeholders are allowed to choose their top-ten 317 requirements from a set of requirements. This approach is suitable when there is a small number of 318 requirements and stakeholders.

319

314

## 320 4. 1. 2 Ordinal Scale

The ordinal scale techniques according to Ma [7] result in an ordered list of requirements. Examples of methods that employ the ordinal scale techniques include the simple ranking method, the bubble sort method, binary search tree and the btree method.

324325 4.1.2.1 Simple Ranking Method

In the simple ranking method, requirements are ranked from 1 to n, where n is any integer value that represents the number of requirements. Requirements with higher priority are ranked 1 while lower priority requirement are ranked n. The advantage of this method is that each requirement has its own numerical value. The drawback of this technique is that it does not provide criteria for categorization [35]. It is also difficult to implement on large number of requirements.

## 332 *4.1. 2.2* Bubble sort

The bubble sort method according to Aho et al. [36] is a method for sorting elements. In this technique, adjacent requirements are compared in a pair-wise manner and swapped if they are in the wrong order. This process continues until no more swaps are required which is an indication that the list of requirement is sorted [37]. The major drawback of the bubble sort method is that it is difficult to evaluate the relative priority differences among the requirements [15].

#### 338 339 *4.1. 2.3 Binary search tree*

The binary search tree is a tree that has a parent-child relationship. The parent node usually contains at most two children [36]. Each parent node in the tree represents a requirement. Requirements with lower priority are arranged on the left side of the parent node while requirements placed on the right side of the parent node are of higher priority. A parent node with no child node is referred to as a leaf. It is however difficult to evaluate the relative priority differences among requirements [37]. In addition, the binary search tree produces unreliable results [38]. Another major criticism of the binary search tree is that it only provides a simple ranking of requirements without assigning any priority values [38].

#### 347 348 *4.1. 2.4 Btree*

Btree uses the same concept as the Binary search tree. The advantage of the Btree method over the binary search tree is that it reduces the number of requirements compared.

### 351 352 **4.1.3 Ratio Scale Method**

The ratio scale is usually believed to be the most viable of all the scales because it has the capacity of ordering, as well as determining intervals or relative difference between requirements. Typical examples of requirement prioritization method that employ the ratio scale method include the hundred dollars or cumulative voting method, Analytic Hierarchy Process (AHP) Cost-Value Approach and the value orientated prioritization.

358

## 359 4.1. 3.1 Hundred Dollar Method

The hundred dollars or cumulative voting method is otherwise known as proportional technique. It was introduced by Leffingwell et al. [39]. The hundred dollars method was designed to determine important requirements by distributing a fabricated \$100 note across requirements according to their degree or level of importance. The requirements are then sorted in ascending order in order to determine the number of dollar notes each requirement has earned. The drawback of this technique is that it is not suitable for a large number of requirements.

366

367 368

## 369 4.1. 3.2 Analytic Hierarchy Process (AHP)

The AHP was introduced by Thomas Saaty in 1980 for complex decision making. AHP was applied to software engineering by Joachim Karlsson and Kevin Ryan in 1997 [40]. AHP involves the pair-wise comparison of requirements in order to determine which of the two is of higher priority and to what extent. If n requirements are to be prioritized using AHP, then n\*(n-1)/2 pair-wise comparisons are required. AHP results in n by n matrix for n requirements. AHP uses a preference scale which generally ranges from 1 to 9, where 1 indicates requirements of equal value and 9 indicates extreme value [41]. The preference scale used for the AHP technique is as shown in Table.1.

- 377 378

388

389 390

391 392

393

394

395

396

397

- The AHP method according to Mead [34] consists of five basic steps which include:
  - 1. The review of candidate requirements for completeness.
    - 2. The application of pair-wise comparison method to assess the relative value of the candidate requirements.
    - 3. Assessing the relative cost of implementing each candidate requirement.
    - 4. Calculate the relative value and implementation cost of each requirement candidate and plot each on a cost-value diagram.
  - 5. Use the cost-value diagram as a map for analyzing the candidate requirements.

One of the major advantages of the AHP is that it is reliable because it computes consistency ratio across requirements to enhance clarity [15]. Another benefit of the AHP is that the resulting priorities are relative and this provides useful assessments of requirements [42]. However, one of the major drawbacks of this technique is that it is not reliable in environments with multiple stakeholders. Hence, the use of AHP seems not feasible with large number of requirements. In addition, AHP is very time consuming. It has also been observed that AHP contains a huge amount of redundancy [43].

405 *4.1. 3.3 Cost-value approach* 

This approach was introduced by Karlsson and Ryan [25]. This approach uses the AHP technique to compare requirements in pair-wise manner based on the relative values and cost of implementing the requirements. However, studies have shown that the Cost-Value approach is also time consuming [15].

410

411 4.1.3.4 Wiegers' Matrix Approach

This technique uses a simple spreadsheet model to estimate the relative priorities for a set of software product feature. This technique is based on weighted assessments of perceived value, relative penalty, anticipated cost, and technical risks. The fundamental difficulty with Wiegers' matrix approach is that the value assigned to a given requirement does not necessarily determine if the requirement meets key business core values.

417 418

## 4.1. 3.5 Hierarchical AHP

The Hierarchy AHP was developed by Karlsson et al. [22] as a refinement of the AHP method. The hierarchical AHP structures requirements in a hierarchy and uses the AHP method to prioritize requirements at the same level of hierarchy. The hierarchical AHP reduces the number of requirements compared in a pair-wise manned as against the AHP method. Hence, redundancy is reduced.

424

## 425 4.1. 3.6 Value Oriented Prioritization (VOP)

VOP prioritizes requirements based on business values and the relative relationships among those
values. This method is not suitable for large projects.

## 429 4.1.4 Machine Learning Techniques

The machine learning techniques use weighting scales or linguistic weights to prioritize requirements based on predefined criteria using learning algorithms [15]. Typical machine learning techniques include fuzzy AHP and Evolve [15].

#### 433 434 *4.1. 4.2 Fuzzy AHP*

The Fuzzy AHP method involves the use of normalized triangular fuzzy weights to rank requirements [44]. This technique is however not scalable and it does not give room for requirements interdependencies [45].

438

## 439 *4.1. 4. 2 Evolve*

Evolve is based on generic algorithm in numerous iterations but has its roots in AHP. In the Evolve prioritization technique, a prioritization matrix is constructed from the weights of the business values of the stakeholders. The major benefits of the Evolve technique are its ability to allow late changes in requirements and changes in the weights assigned to stakeholders [31]. Evolve does not support requirements evolution or rank update [46].

### 445 446 **4.1. 5 Hybridized Techniques**

These techniques combine the features of the nominal scale, ordinal scale and the ratio scale methods. Requirement prioritization methods under this category include the Planning Game method, requirement triage [7].

450

# 451 4.1. 5.1 Planning game

452 This method is based on extreme programming [47]. The planning game combines the numerical 453 assignment technique and ranking technique to perform requirements prioritization. Requirements 454 according to Beck [48] are first prioritized into three groups which include those without which the 455 system will not function, those that are less essential but provide significant business value, and those 456 that would be nice to have. After assigning the requirements into the three groups, the programmer 457 estimates how long time each requirement would take to implement and then begin to sort the 458 requirements into three different groups. This method does not scale well with large number of 459 requirements.

460

## 461 4.1. 5.2 Requirements triage

462 The word triage has its origin in the medical field. The word triage was used to classify patients based 463 on how much benefit they derive from medical treatment. For instance, during a triage, disaster 464 victims were categorized into three groups; those that would only recover if they receive medical 465 attention, those that would recover regardless of treatment, and those with no hope of recovery. 466 Hence, requirements triage is aimed at establishing the relative priorities for requirements by 467 estimating the resources necessary to satisfy each requirement [34]. At this point, the stakeholders 468 determine the requirements that must be included and those that must be excluded. This process 469 leaves a set of requirements which the stakeholders can choose from. Thereafter, requirements that 470 are more important are prioritized by AHP, simple ranking or \$100 method.

471

## 472 **4.2 Requirement Negotiation**

473 Requirements negotiation focuses on the assignment of priorities to requirements through the 474 consensus of the stakeholders. Typical example of requirement negotiation is winwin method, multi-475 voting system and ping pong balls.

#### 476 477 **4.2.1 Winwin**

In the winwin technique, the stakeholders agree on the requirements that are of utmost importance to
them. The major difficulty of this technique is that the stakeholders might have difficulty in agreeing on
the requirements [14]

### 481 482 **4.2.2 Multi voting system**

This technique allows stakeholders to vote for the requirements that are of utmost importance to them. The requirements with the highest number of vote are considered the most important.

## 485 486 <u>4.3.3. Ping Pong Balls</u>

In the ping pong balls technique, stakeholders are given ping pong balls which represent each of the requirements. Stakeholders are then asked to choose from the ping pong balls. The requirement with the highest priority is determined by the highest number of ping pong balls chosen. This method is not effective when large number of stakeholders is involved.

## 492 4.3.4. Dot Voting

In dot voting, stakeholders are requires to rank requirements with sticky dots. Requirements with
 higher dots are considered more important. Again, this technique is not suitable for larger number of
 stakeholders and requirements.

496

491

## 497 5.0 A COMPARATIVE ANALYSIS OF REQUIREMENT PRIORITIZATION TECHNIQUES

This section reviews requirement prioritization techniques based on scalability, reliability with multiple stakeholders, cost, time consumed, ease of use and consistency check. Table 2 shows a comparative analysis of requirement prioritization techniques.

501 502

503

## Table 2. A Comparison of Requirement Prioritization Techniques

	Requirement Prioritization Technique	Scale of Measurement	Scalability/ ability to handle large number of requirements	Reliability with multiple stake holders	time consumed	ease of use	users' confidence	consistency check

## Fig.4. Characteristics of Requirement Prioritization Techniques

In Table 2 and Fig. 4, twenty one requirement prioritization techniques were compared. The study examined three nominal scale requirement prioritization methods. These methods include numerical assignment, top-ten requirements and Moscow. Table 2 shows that these methods are not scalable when multiple requirements are involved in requirement prioritization. In addition, these methods are not reliable when multiple stakeholders are involved in requirement prioritization. The time taken to prioritize requirements with these techniques is low. These methods are easy to use and users' 516 517 confidence is high when using these techniques are deployed for requirement prioritization. However, 518 these methods lack the facility for consistency check. The study also examined four ordinal scale 519 methods, specifically, simple ranking method, bubble sort, binary tree and B-Tree. These methods are 520 also not scalable when diverse requirements are involved in requirement prioritization; they are not 521 reliable when multiple stakeholders are involved in requirement prioritization and they do not consume 522 so much time during requirement prioritization. The findings from the study also revealed that these 523 techniques are easy to use and the users' confidence is high. AHP, hierarchical AHP, Weigers' Matrix,

524 cost value and VOP were the requirement prioritization techniques studied based on ratio scale. The 525 study revealed that these methods are not scalable when multiple requirements are involved in 526 requirement prioritization; they are not reliable when multiple stakeholders are involved in requirement 527 prioritization, they are not easy to use and users' confidence is low. Cost value, Weigers' Matrix and 528 VOP do not consume so much time during requirement prioritization, while the time taken to prioritize 529 requirements with AHP, hierarchical AHP is high. However, the ratio based requirement prioritization 530 techniques compared have the facility for consistency check. Furthermore, two hybridized 531 requirement prioritization methods were also studied. These include the planning game method and 532 the requirement triage. These methods are also not scalable when multiple requirements are involved 533 in requirement prioritization and they are not reliable with multiple stakeholders. However, the time 534 taken to prioritize requirements with planning game techniques is high; while it takes less time to 535 prioritize requirements with requirement triage. Both methods are easy to use and users' confidence 536 with both methods is high. In addition, four requirement negotiation techniques were studied. These 537 techniques include multi-voting, win-win, dot voting and ping-pong. The result of this study further 538 revealed that these methods are not scalable when numerous requirements are involved, they are not 539 reliable with several stakeholders, they require less time for requirement prioritization, they are easy 540 to use and users' confidence is high when using these techniques for requirement prioritization. 541 However, they lack the facility for consistency check. It can therefore be deduced from Table 2 that 542 the users' confidence and ease of use are directly proportional. Hence, the easier the requirement 543 prioritization technique, the more confident the user is with the technique. Hence, user confidence is 544 low for techniques such as Analytic Hierarchy Process, Fuzzy AHP and Cost-Value approach which 545 are relatively difficult to use. 546

## 547 6. CONCLUSION

548

549 Requirement prioritization is one of the major activities carried out during requirement analysis 550 process. Requirements prioritization refers to the process of selecting the appropriate set of 551 requirements from a multitude of competing and conflicting expectations elicited from various 552 stakeholders involved in a software development project. There are several techniques used for 553 prioritizing requirements. These prioritization techniques can be categorized as requirement 554 prioritization method and requirement negotiation. The requirement prioritization method is based on 555 five basic scales which include nominal scale, ordinal scale, ratio scale, machine learning and 556 hybridized techniques. The requirement negotiation involves techniques such as winwin, multi-voting 557 system and ping pong balls. However, the reliability of these requirement prioritization techniques is 558 usually a challenge when multiple requirements and stakeholders are involved during requirement 559 prioritization. Hence, this study compared twenty one requirement prioritization techniques such as 560 Numerical Assignment Technique, Simple Ranking Method, Hundred Dollar Method, Analytic 561 Hierarchy Process, Fuzzy AHP, Cost-Value approach, bubble sort method, binary search tree, 562 winwin, multi-voting system and the MosCow technique. The comparison was based on scalability, 563 reliability with multiple stakeholders, time consumed, ease of use, users' confidence and consistency 564 check. This was with a view of assisting stakeholders to determine which technique is best to prioritize 565 software requirements. The study revealed that AHP and hierarchical AHP consume more time than 566 other techniques during requirement prioritization. It can also be deduced from the study that AHP, hierarchical AHP, Fuzzy AHP, VOP and Evolve are more difficult to use when compared with other 567 techniques. Furthermore, of all the techniques compared, AHP, hierarchical AHP, cost value, fuzzy 568 569 AHP and VOP have facilities for consistency check. The result of the study also showed that all the 570 techniques compared are not scalable. Hence, it is difficult to prioritize requirements when multiple 571 stakeholders are requirements are involved in the software development process. Hence, future 572 researches should be based on the design of a requirement prioritization technique that will have the 573 ability to accommodate large stakeholders and requirements.
