Original Research Article Effect of Planting Density on Biomas Cf Acacia Plantations in Northeast Vietnam

5 Abstract

Acacia plantations have been contributing to national economic and livelihood of millippeople living 6 7 in rural areas of Vietnam. It has been widely planted and accounted for nearly 50% areas of plantations in Vietnam. In this study, different planting densities including 1,110 trees ha⁻¹ (3×3 m), 1,330 trees ha⁻¹ 8 $(2.5 \times 3 \text{ m})$, and 1,660 trees ha⁻¹ $(2.5 \times 2.5 \text{ m})$ were tested for *Acacia hybrid* and *Acacia auriculiformis*. 9 10 The growth parameters (diameter at breath height/DBH and stem height/H) were measured and dry 11 biomass was estimated for 4-year-old plantations. The results indicated that a 4-year-old plantation of A. hybrid had largest DBH (11.3 cm) at planting density of 1,100 tree happened by biomass 12 (57.9 Mg h planting density of 1,660 trees have $\frac{1}{2}$ leanwhile, a 4-year-old plantation of A. 13 auriculiformis had large BH (10.0 cm) and highest dry biomass (50.4 Mg ha⁻¹) at planting density of 14 1,330 trees 1 At the same planting densities of 1,110 trees ha⁻¹ and 1,660 trees ha⁻¹, a 4-year-old 15 plantation of *A. hybrid* had significantly higher dry bioma plantation 16 of A. auriculiformis. Meanwh () the difference of dry biomass between 4-year-old plantations of two 17 species at planting density of 1,330 trees ha⁻¹ was n planting 18 *hybrid* planting densite $\int 1,660$ trees ha⁻¹ should be used, while density of 1,330 trees ha⁻¹ is encouraged 19 20 for planting A. auriculiformis for pulp wood production.

25 **1. INTRODUCTION**

Plantations of exotic trees are assuming an increasingly significant role in landscape management and the rural economy in many tropical regions [1]. In Vietnam, plantation of acacias is becoming increasingly important in contributing to the national economy and livelihood of million people in rural areas [2], when logging timber from natural forest is prohibited. By 2013, 51% of total plantation areas in Vietnam were planted with acacias.

31 To protect natural resources and the environment for the sustainable development, plantation

has become the major source of timber supply for timber industry such as solid wood, plywood pulping, and paper [3]. A good plantation species shout produce not only high timber yield, but also the desired properties of wood for highly valued end products. Accelerating tree growth or shortening the rotation could potentially affect wood quality [4].

Acacias are the major raw material of the pulp and paper industries in Vietnam and for export, so it is imperative that planting stock of high genetic quality is important to increase productivity for acacia plantations. Silviculture techniques as selecting optimum densities and fertilization application are important management considerations to increase overall productivity for any plantation [5]. Planting density is a very important tool of silvicultural treatment, which affects the growing conditions of planted trees and the stem wood production [6].

The objective of this study is to examine the effects of planting density on growth of acaciaplantations in Northeast Vietnam.

45 2. MATERIALS AND METHOD

46 **2.1 Study Site**

47 This study was conducted in Quang Ninh Province in Northeast Vietnam, on the altitude of 85–100 m

48 above sea level. The site has mean annual temperature of 23°C and total annual precipitation of 1,850–

49 1,900 mm. Soil in the study site is known as Ferralic Acrisol with average pH of 3.5–3.6, organic

50 matter of 3.2–4.3%, and nitrogen of 0.069–0.164% [7].

51 **2.2 Plantation Establishment**

Two wide-planted acacia species including *Acacia auriculiformis* and *Acacia hybrid* were experimented
 in this study.

54 The experiment on planting density included three treatment as (a) 1,110 trees ha⁻¹ (3×3 m), (b) 1,330

55 trees ha⁻¹ (2.5 × 3 m), and (c) 1,660 trees ha⁻¹ (2.5 × 2.5 m). At planting, each tree was fertilized

56 with 150 g NPK (ratio of 5:10:3) + 150 g compost.

Experiment was conducted in a randomized complete block with three replicates. Each treatment was conducted in a plot of 20×20 m, which included 36 trees in planting density of 1,110 trees ha⁻¹, 42 trees in planting density of 1,330 trees ha⁻¹, and 49 trees in planting density of 1,660 trees ha⁻¹. Totally, there were two blocks for two study specie

62 2.3 Data Collection and Analysis

- 63 Data included survival rate (%), diameter at breast height (DBH in cm) and stem height (H in
- 64 m) were measured after planting four year Ω Il surviving stems in plots were measured.
- 65 Total dry biomass of each stem (B in kg) was estimated as following [8]:
- 66 *A. hybrid* $B = 0.2255*DBH^{2.1661}$
- 67 A. auriculiformis $B = 0.3116*DBH^{2.1069}$

68 Comparison among treatments in each species was conducted with ANOVA one-factor and

69 post-hoc test. While, comparing between two species in each planting density was conducted

- 70 by pair-comparison. Statistical analysis was conducted by using SAS 9.2.
- 71

72 **3. RESULTS**

- 73 Survival rates of A. hvbrid plantation were higher than 94% in all treatments (Table 1) after planting four years. The highest survival rate was 95.3% in planting density of 1,330 trees ha⁻¹, and the lowest (94%) 74 belonged to planting density of 1,110 trees ha⁻¹. However, the difference of survival rates among three 75 76 planting densities was not statistically significant. The highest mean stem height (13.6 m) was found in 77 planting density of 1.330 trees ha⁻¹ and the shortest mean stem height (13.4 m) was found in planting density of 1,110 trees ha⁻¹. Similar with survival rates, planting densities did not significantly effect on 78 79 height growth of A. hybrid (Table 1). Meanwhile, planting density significantly effect on DBH growth 80 and dry biomass. The largest mean DBH (11.3 cm) was found in planting density of 1,110 trees ha⁻¹, reducing to 10.9 cm in planting density of 1,330 trees ha⁻¹, and to 10.5 cm in planting density of 1,660 81 trees ha⁻¹. Even owning less smalle be an DBH, a 4-year-old plantation of planting density of 1,600 82 trees ha⁻¹ had highest dry biomass (57.9 Mg ha⁻¹). The lowest dry biomass (44.9 Mg ha⁻¹) belonged to 83 84 planting density of 1,110 trees ha⁻¹ (Table 1).
- 85

86 Table 1. Effects of planting density on survival rate, growth, and dry biomass of a 4-year-old *A*.
 87 *hybrid* plantation (means ±SD)

Planting density (the ha ⁻¹) [spacing]	rees Survival rate (%)	DBH (cm)	Н	(m)	Dry biomass (Mg ha ⁻¹)
1,110 [3 × 3 m]	94.0 ±0.57	11.3 ± 0.81^{a}	13.	4 ±0.65	44.9 ± 1.3^{a}

1,330 [2.5 × 3 m]	95.3 ±2.08	$10.9\pm\!\!0.79^{ab}$	13.6 ±0.71	50.5 ± 2.8^{a}
1,660 [2.5 × 2.5 m]	95.0 ±0.57	10.5 ± 0.85^{bc}	13.5 ±0.59	$57.9\pm\!\!1.8^{b}$

88 In a column, the different letters ^{a, b, c} indicated the significant difference of mean at p = 0.05. 89

90 Survival rate of a 4-year-old A. auriculiformis plantation was highest (95%) in planting density of 1.330 trees ha⁻¹, reducing 94.7% in planting density of 1,660 trees ha⁻¹, and to 94% in planting density of 91 1,100 trees ha⁻¹ (Table 2). However, planting density did not significantly effect on survival rates after 92 planting four years. Mean DBH (10 cm) was largest at planting density of 1,300 trees ha⁻¹ and the 93 smallest mean DBH (8.4 cm) was found in planting density of 1,660 trees ha⁻¹. The difference of mean 94 95 DBH among three planting densities was statistically significant. Planting densities also significantly 96 effect on height growth and dry biomass of a 4-year-old A. auriculiformis plantation. Mean height was tallest (10.3 m) in planting density of 1,300 trees ha⁻¹, reducing to 8.8 m in planting density of 1,110 97 trees ha⁻¹, and to 7.8 m in planting density of 1,660 trees ha⁻¹. Resulted from largest mean DBH, 98 plantation with planting density of 1,330 trees ha⁻¹ had highest dry biomass of 50.4 Mg ha⁻¹, and the 99 lowest dry biomass (34.9 Mg ha⁻¹) belonged to planting density of 1,100 trees ha⁻¹. 100

101

Table 2. Effects of planting density on survival rate, growth, and dry biomass of a 4-year-old A.
 auriculiformis plantation (means ±SD)

Planting density (trees ha ⁻¹) [spacing]	Survival rate (%)	DBH (cm)	H (m)	Dry biomass (Mg ha ⁻¹)
1,110 [3 × 3 m]	94.0 ± 0.58	9.2 ± 0.85^{a}	8.8 ± 0.69^{a}	34.9 ± 0.4^a
1,330 [2.5 × 3 m]	95.0 ± 0.58	10.0 ± 0.88^{a}	10.3 ± 0.72^{b}	50.4 ± 0.5^{b}
1,660 [2.5 × 2.5 m]	94.7 ± 0.33	$8.4\pm\!\!0.71^b$	$7.8 \pm 0.59^{\circ}$	$43.4\pm0.3^{\circ}$

104 In a column, the different letters ^{a, b, c} indicated the significant difference of mean at p = 0.05. 105

At the planting density of 1,330 trees ha⁻¹, a 4-year-old *A. auriculiformis* plantation had dry biomass of 50.4 Mg ha⁻¹ and that of a 4-year-old *A. hybrid* plantation was 50.5 Mg ha⁻¹. The difference of dry biomass between two species at this planting density was not significant (Fig. 1). Meanwhile, the difference of dry biomass between two species was statistically significant at planting densities of 1,100 trees ha⁻¹ and 1,660 trees ha⁻¹. Whice dicated that dry biomass of a 4-year-old plantation of *A. hybrid* was significantly higher than that of a 4-year-old plantation of *A. auriculiformis*. The difference was 10

- 112 Mg ha⁻¹ at planting density of 1,110 trees ha⁻¹ and 14.5 Mg ha⁻¹ at planting density of 1,660 trees ha⁻¹.
- 113
- 114

Fig. 1. Comparison of dry biomass between a 4-year-old plantation of *A. hybrid* and that of *A. auriculiformis* at different planting densities. Vertical bars indicated \pm SD. Asterisks indicated the significant difference of dry biomass in corresponding planting density at *p* = 0.05.

119

120 4. DISCUSSION

121 Each tree requires a growing space of both belowground and aboveground. Requirement of growing 122 space is increasing with tree's age and/or growth of crown and root's systems. When there is no 123 competition for growing space as no-cross growth of crown and/or root's system, trees grow freely and 124 tend to have large crown and DBH but shorter stem height. The planting density represents growing 125 space of planted trees. The denser planting density is, the less growing space trees have. It is obviously 126 that growing space for planted trees of both A. hybrid and A. auriculiformis is largest at planting density of 1,110 trees ha⁻¹ (9 m² tree⁻¹), reducing to 1,330 trees ha⁻¹ (7.5 m² tree⁻¹), and to 1,660 trees ha⁻¹ (6.25 127 m^2 tree⁻¹). Dang [7] indicated that at the same age, crown diameter of A. hybrid is larger than that of A. 128 *auriculiformis*, when both were planted he same site. Therefore, in this study the growing space is 129 130 more available for A. auriculiformis tree than that for A. hybrid tree at the same planting density.

- 131 The larger growing space at planting density of 1,110 trees ha⁻¹ led to less competition among planted
- 132 trees of A. hybrid. Therefore, mean DBH was largest in planting density of 1,110 trees ha⁻¹ and smalle
- 133 in planting density of 1,660 trees ha⁻¹ (Table 1). This pattern was not found for *A. auriculiformis* (Table

UNDER PEER REVIEW

2), which had largest mean DBH at planting density of 1,330 trees ha⁻¹. However, mean DBH at both planting densities of 1,110 trees ha⁻¹ and 1,330 trees ha⁻¹ was not significantly different. This may be explained by small crown diameter of both planting density [7] which led to no completion among planted trees, and species characteristics of *A. auriculiformis* [9]. While, there was cross-crown of planted trees at planting density of 1,660 trees ha⁻¹, leading to significant smaller mean DBH in this

- 139 planting density of *A. auriculiformis* (Table 2).
- 140 There was no significant difference of stem height among planting densities for A. hybrid (Table 1),
- 141 while it was for *A. auriculiformis* (Table 2). Even it was mentioned that crown diameter of *A. hybrid* is
- 142 much larger than that of *A. auriculiformis* [7], leading to higher competition of *A. hybrid* compared to
- 143 that of *A. auriculiformis* at the same planting densities [10]. This is explained by species characteristics.
- 144 Of which, A. auriculiformis is usually taller in stem height and thinner in DBH [9] compared to A.
- 145 *hybrid* when they are planted in the same site with the same silvicultural techniques.
- Dry biomass of individual stem is function of DBH. Therefore larger DBH stem has higher biomass [8, 147 11]. In addition, dry biomass per area unit is function of both stem DBH and planting density [8]. 148 However, mean DBH and planting density have negative relationship; higher planting density leads to 149 smaller mean DBH. Such correlation resulted in difference of dry biomass of plantation [12]. Smallest 150 mean DBH with highest planting density of 1,660 trees ha⁻¹ for *A. hybrid* led to highest biomass of a 4-151 year-old plantation (Table 1). Meanwhile, largest mean DBH with medium planting density of 1,330
- 152 trees ha⁻¹ resulted in highest dry biomass of a 4-year-old *A. auriculiformis* plantation (Table 2).
- 153 Dhe plans to grow *A. hybrid* and *A. auriculiformis* for pulp wood production, planting density of 1,660
- 154 trees ha⁻¹ is best applied for A. hybrid and that is 1,330 trees ha⁻¹ for planting A. auriculiformis. However,
- 155 higher planting density requires higher inputs as costs for seedlings, soil preparation, and fertilization *etc.*
- 156 Therefore, cost-benefit analysis should be considered before practicing.
