3 **SELECTING A REPRESENTATIVE SAMPLE**
4

5 **ABSTRACT**

6 *The output of any research work depends, to a reasonable extent, on the adequacy of the*
7 *sample from which data are obtained for the research. A sample is adequate when it is*
8 *representative of the population or when it possesses the characteristics that are typical of the*
9 *population from which it is drawn. The focus of this paper is on how researchers can select*
10 *samples that are really representatives. Descriptive method was utilized in the writing of the*
11 *paper. Attempts are made, in the paper, to describe the concepts of sample representativeness,*
12 *sampling methods and sampling error. Some suggestions are then made on measures to take*
13 *in carving out truly representative samples.*

14 *Keywords: Selection, Sample, Representative sample.*
15

16 **INTRODUCTION**

17 Information Technology has dominated the world today and radical
18 technological change and fusion have changed the way work is organized and
19 performed [7]. To this end, frantic efforts are made to obtain relevant information on
20 different aspects of human life.

21 Managers are fond of making decisions on different areas of business management
22 in order to achieve organizational objectives. The decision making process requires
23 certain information that will provide essential clues to certain issues. The
24 information so needed could be derived from hundreds or thousands of prospective
25 respondents who could be consumers, suppliers, employees, scholars or
26 government officials. As a result of the largeness of the population being dealt with,
27 a researcher may need to carve out just a fractional segment of the entire population
28 to ensure easy and timely collection of data. Herein lies the relevance of sampling.

29 It is one thing to create a sample out of a particular population; it is another
30 thing to ensure that the sample is large enough to represent the population. By
31 population, we mean the totality of items in an investigation [10]. In other words,
32 population is a collection of the individual items that are to be observed in a given
33 problem situation; the items could be living or non-living things.

34 A sample is a selected portion or subset of the population being investigated
35 [18]. The elements in the sample possess the same characteristics with the
36 population but the differences are in the size; that is, sample < population [4].

37 A quality control manager may decide to take a few cocoa beans, say 50, from a
38 bag of cocoa to investigate the quality level of the content of the bag. The thinking of
39 the quality control manager is that by examining 50 out of the entire cocoa beans in

40 the bag, he will get a fair notion of the quality of the entire population cocoa beans
41 inside the bag.

42 The objective of this paper is to find answers to the following questions:

- 43 i. What are the different methods of creating samples?
- 44 ii. What should be done to ensure selection of a truly representative sample?
- 45 iii. How can sampling errors be reduced?

46 In view of the nature of this study, descriptive method was used in writing, the
47 paper.

48 Towards this end, efforts were made to describe sampling methods, sample
49 representativeness and sampling error.

50

51 **SAMPLING METHODS**

52 [12] defines sampling as the process of taking any part of a population or
53 universe as representative of that population or universe. Another way of saying the
54 foregoing is that sampling is a means of estimating population parameters from only
55 a few items. The process takes place especially when the population being studied is
56 a large one such that it becomes impossible or costly to investigate each item in it
57 (population). What could be done in that situation is to select a few elements from
58 the whole of materials being investigated and then make a generalization about the
59 population [3]. The method by which sample was drawn determines, to a reasonable
60 degree, the extent to which generalizations about the population can be made [17].
61 The sampling method so used determines the representativeness of the sample in
62 relation to the population.

63

64 Sampling methods can be categorized into two main classes namely,
65 probability sampling techniques and non-probability sampling techniques.

66

67 **Probability Sampling Methods**

68

69 These are sampling techniques for which we can determine the chance of
70 drawing each member of the population to form a sample. The method describes a
71 situation in which each item within the population has equal chance of being chosen
72 to form a sample [21]. Thus, there is no bias in the selection of sample members. One
73 other major advantage of this set of sampling methods is that it is easy to measure
74 the sampling error and interpret sampling results. As a result of these favourable
75 features, conclusions reached by studying a particular sample are considered
76 generalizable to that population or other similar populations.

77

78 Some of the probability sampling methods are listed below

79 Simple random sampling

- 80 Stratified sampling
- 81 Systematic sampling
- 82 Cluster sampling

83
84 **Simple Random** Sampling: This sampling method Involves selecting a few elements
85 from a total population in such a way that each member of the population has an
86 equal chance of being selected. Thus, a sample drawn at random is unbiased in the
87 sense that no member of the population has any more chance of being selected than
88 any other member [20].

89
90 One means of carving out a sample from the entire population is to name or number
91 each item in the population. Next, each name or number is cut into a small slip and
92 squeezed and then placed in a container. The investigator puts his hand into the
93 container to pick the number of slips required to obtain the required size of the
94 sample.

95
96 The selection procedure described above may not be possible in a situation where
97 the studied population is very large. For instance, taking a random sample of the
98 population of Lagos State, a table of random numbers, an example of which is
99 shown in Table 1, becomes useful. The computer is often used to accomplish the
100 selection process at this level.

117

118 **Stratified Sampling:** According to [1], stratified sampling method is best suited to
119 populations that have different sets of groups within them. In other words, the
120 sampling method is mostly used when dealing with heterogeneous populations. For
121 instance, if a researcher wants to collect relevant data on a topic that says "Life after

122 death" from a set of people, the best sampling method to use is stratified sampling.
 123 The reason being that the population being sampled will comprise people of
 124 different religious beliefs who are bound to have different opinions on the subject
 125 matter. In this case, the heterogeneous population will have to be divided into three
 126 homogeneous groups or strata as follows; Christians, Muslims and Traditional
 127 believers.

128
 129 [17] maintains that there are two types of stratified sampling namely,
 130 proportionate stratified random sampling (**PSRS**) and disproportionate stratified
 131 random sampling (**DSRS**). In **PSRS**, the population is first stratified in terms of one
 132 or more variables of interest to the researcher. Elements are drawn randomly from
 133 each stratum in such a way that the relative proportions of the strata in the resultant
 134 sample are the same as exist in the parent population. This is saying that the relative
 135 contribution of each stratum in the population is exactly its relative contribution in
 136 the sample.

137
 138 [17] and [18] were of the view that **PSRS** ensures greater representativeness of
 139 the sample relative to the population and guarantees that minority constituents of
 140 the population are represented in the sample. Table 2 below illustrates **PSRS** with a
 141 population of 1220 entrepreneurs.

142
 143 Table 2: Distribution of a population of 1220 entrepreneurs according to
 144 categories/sizes.

	Entrepreneurs			
	Small-Scale	Medium-Scale	Large-Scale	Total
Population Size	549	427	244	1220
Proportion	0.45	0.35	0.20	1.00

146
 147 Table 3: Proportionate stratified random sample for a population of 1220
 148 entrepreneur.

	Entrepreneurs			
	Small-Scale	Medium-Scale	Large-Scale	Total
Population Size	549	427	244	1220
Proportion	0.45	0.35	0.20	1.00
Sample Size	110	85	49	244

150
 151 In case of disproportionate stratified random sampling, the relative proportions of
 152 the strata in the sample do not correspond to their relative proportions in the
 153 population. Some strata may be under-represented or over-represented in the
 154 sample. Obviously, this sampling mode allows the researcher the freedom of
 155 weighting the various strata in any manner he considers fit. Though the method
 156 does not make for proper representativeness, [18] was of the opinion that the **DSRS**

157 method is preferred where the researcher believes that there is likely to be great
158 within-stratum variation in responses or if he has a particular interest in one or more
159 strata.

160

161 **Systematic Sampling:** It is also called quasi-random sampling. In this method, the
162 first sample element is randomly chosen from numbers I through K and subsequent
163 elements are chosen at every Kth interval [12]. K will be determined by the size of the
164 sample required. For example, if the population of Texy University is 16,000 and a
165 list of all the students making up the population is available. If a sample of 200
166 students is to be taken, the selection of every 80th student will give the required
167 sample.

168

The value of K above is determined as follows.

169

$$\frac{\text{Total Population}}{\text{Required sample}} \quad \text{That is, } \frac{N}{n}$$

172

173

174

Therefore,

175

176

$$K = \frac{16,000}{200} \\ = 80.$$

177

178

179 It must be noted that systematic sampling is used only when the list of all items in a
180 population is available as in the case of a class register. The question as to how to
181 determine the first element that will form the sample is answered by choosing a
182 number at random between I and 50.

183

184 **Cluster Sampling:** Cluster sampling is otherwise known as area sampling. It is
185 successive random sampling units or sets and subsets [2]. In selecting a sample
186 using this method, the population (or geographical area) is divided into units or
187 segments with well-spelt-out boundaries. A specified number of these units or a
188 section is drawn. All elements in the units or sections drawn now constitute the
189 sample.

190

191 As observed by [18], cluster sampling is used when it can be recognized that
192 some populations are distributed in clusters or groups of settlement and these
193 clusters are to be used as the basis for sampling.

194

195 [8] affirms that unlike stratified sampling, using cluster sampling does not
196 require a list of the elements in the population before sample can be drawn. As long
197 as these are distinguished clusters or geographical locations, creating samples
198 becomes feasible.

199

200 **Non-Probability Sampling Methods**

201 Non-probability sampling is non-scientific approach to sample formation [15]. It is
202 the process of getting samples from populations without following any statistical

203 rules. The researcher or investigator uses only his intuition to select sample members
204 is fraught with bias and partiality simply because each item in the population does
205 not have an equal chance of being selected. The ultimate consequence of this
206 abnormality is that it becomes difficult to measure the sampling error and to
207 interpret results.

208 The following techniques are examples of non-probability sampling methods:

209 Judgmental sampling

210 Quota sampling

211 Convenience sampling

212 Snowball sampling

213 **Judgmental Sampling:** This involves the use of the researcher's reasoning and
214 judgment to obtain a sample, what determines whether an item in the population
215 will be selected or not into the sample is the personal preference of the investigator.

216 Sampling here is influenced by the personal bias of the person or group of persons
217 selecting members for the sample. That is not to say, however, that judgment
218 sampling is a complete write-off. It is advantageous in the sense that it saves time as
219 the process does not require any listing or numbering of the population or random
220 number tables [20].

221 **Quota Sampling:** According to [17], this involves selecting those elements that have
222 specific characteristics of interest to the researcher and are accessible to him. This
223 type of sampling is used to ensure that specific elements will be included.

224 Evidently, quota sampling gives room for the researcher or investigator to include
225 any category of the population that is of particular interest to him. It is quicker,
226 easier and cheaper. It is disadvantageous in the sense that the resultant sample is
227 highly biased and thus, cannot be said to be representative [11].

228 **Convenience Sampling:** The major consideration of the researcher using this
229 sampling method is the ease of selecting the sample. The researcher makes no
230 attempt to bring in any element of randomness. He selects members of the sample in
231 a way that is convenient or easy for him.

232 As an illustration, a student of Adekunle Ajasin University, Akungba-Akoko,
233 Nigeria, researching on the topic "The problem of small-scale business entrepreneurs
234 in Ondo State" may decide to get the required sample of small-scale business
235 entrepreneurs from Ikare-Akoko and Owo. This is because the two towns are very
236 close to his institution of research and so, can easily or conveniently collect the
237 needed data from respondents in the two towns.

238 In fact, the researcher does not know how well a Convenient Sample will represent
239 Sample the population regarding the traits or mechanism under research. What

240 makes convenience sample so unpredictable is their vulnerability to severe hidden
241 biases. [14].

242 Therefore, in convenience sampling, the individuals selected by the researcher may
243 not be applicable to the research problem.

244 Hence, there is a rise of collecting poor quality data due to poor outcomes such as,
245 difficulty to convince others to accept the findings or research based on poor
246 foundation. [19]

247 **Snowball Sampling:** This method is often used to obtain samples in situations
248 where there is no adequate list which could be used as a sampling frame [20].
249 Towards this end, the researcher contacts a member of the population of interest or
250 identifies a group of respondents who possess the traits desired for the research
251 work [18]. This set of people will in turn, identify another set of people suitable for
252 the research work. This chain continues.

253

254 SAMPLING ERROR

255 Sampling error simply means deviation from population values. It is the difference
256 between the result obtained from a sample and the result which would have been
257 obtained from the population. This type of error often occurs when tile complete
258 survey of the population is not carried out, but a sample is taken for estimating the
259 characteristics of the population [9]

260 When the entire population is considered no sampling error occurs. The occurrence
261 of sampling error when a sample is carved out of a population depends on the size
262 of the sample relative to the population. As shown in Figure 1, the smaller the
263 sample the larger the error, and the larger the sample the smaller the error.

264

275
276
277
278
279
280
281

282 Figure 1: Sample size vis-à-vis sampling error

283
284 It is possible to measure the sampling error [21]. The error is measured by the
285 standard error of the statistics in terms of probability under the normal curve. The
286 result of the measurement indicates the precision of the estimates of the population
287 based on the sample study [20].

288
289 Sampling error is derived by calculating the standard error of sample mean. It is the
290 standard deviation of the sampling distribution of sample means [3]. It is denoted by
291 $\bar{\sigma}_x$ and is given by

$$\bar{\sigma}_x = \frac{\bar{\sigma}}{\sqrt{n}}$$

292
293 Where

294 $\bar{\sigma}$ = Standard deviation of the population

295 n = sample size

296
297
298 It is often advocated that large samples should be used. They are advocated
299 in order to give the principle of randomization a chance to work [12].

300 301 **SAMPLE AND REPRESENTATIVENESS**

302 The word “representative” means to be typical of a population; that is, to
303 exemplify the characteristics of the population. The fact that a segment of a
304 population is taken as representative of that population does not mean that the sample,
305 so taken, is representative. For example, a researcher investigating a banking habit in
306 First Bank Plc, may decide to draw his sample from two branches of First Bank in
307 Lagos, Nigeria, thereby assuming that the two branches represent the total
308 population of the bank's branches. That sample selection may be wrong as data and
309 opinions collected from the two branches may not be representative of what actually
310 happens in the entire First Bank Plc network. That goes to show that too small
311 samples are not good enough as they tend not to represent the characteristics of the
312 population. This will eventually result in getting results that are likely to be lacking
313 in validity.

314 [12] opines that in research, a “representative sample” means that the sample
315 has approximately the characteristics of the population relevant to the research in
316 question. If sex and socio-economic class are characteristics relevant to the research,
317 a representative sample will have approximately the same proportions of men and
318 women and middle class and working class individuals as the population.

319
320 The question as to how large a sample must be to be adequate or to be truly
321 representative is not a simple one. Each situation presents its own problems. If the
322 phenomena under study are homogenous, a small sample is sufficient. If units under
323 study are variable, a much larger sample is needed. The greater the variability of the
324 phenomena, the greater the difficulty of obtaining an adequate sample. But that is

325 not to say that using very large samples is always wise. Making use of samples that
326 are too large amounts to waste resources - money, time and energy.

327

328 In order to obtain a representative sample, the following points need to be
329 borne in mind by the researcher.

330

331 1. There is need for care and precision on the part of the researcher. He must
332 take care to see that the sample drawn from the population is not biased.
333 Towards this end, it is preferable to use probability sampling methods in
334 selecting sample members since such a procedure guarantees that every
335 population element has equal chance of being selected.

336 2. The population being investigated must be properly defined. It should be
337 defined in terms of four things namely, the element, sample unit, extent and
338 time [16]. For instance, a survey of consumers might specify a relevant
339 population as follows:

340

341 3. Elements : Male
342 Sampling Unit : 27-35 years
343 Extent : Kaduna State, Nigeria
344 Time : As at 30th October, 2016

345

346 In the alternative, the population for a study designed to measure buyers' reaction to
347 a new pharmaceutical item may be the following:

348 Element : Pharmacists
349 Sampling Unit : Pharmaceutical companies buying over
350 ₦5 million worth of item per year.
351 Extent : Enugu State, Nigeria
352 Time : Year 2014

353 The essence of defining studied population properly is to ensure that whatever data
354 are obtained from the selected sample meet the researcher's expectation in terms of
355 data currency, respondents/interviewer's level of experience and
356 geographical/professional coverage.

357

358 4. The usual thing to do after identifying a population is to obtain a complete
359 and current list of all elements in the population. Nonetheless, in order to get
360 a representative sample, the researcher should avoid drawing a sample by
361 preparing an alphabetical list and proceeding down the list until he has
362 included a sufficient number in the sample. Some letters of the alphabet
363 include more names from certain groups than others, and this may produce
364 bias in the sample on the basis of name alone.

365 5. The idea of allowing interviewers to select interviewees who are like
366 themselves should be discouraged. Such a habit results in a biased sample.
367 For example, if interviewers or researchers are members of a particular
368 religion, they will likely select many interviewees from the same religion and
369 include just a few individuals from other religions. Samples obtained through
370 such an awkward procedure will produce opinions and data that are not

371 representative of the entire population [11].
372 6. [18], in his own contribution, opines that samples must be adequate enough to
373 generate generalizable result of findings. There is need for researchers or
374 investigators to ensure that the elements that make up a particular sample are
375 those that possess the features that are typical of the entire population.
376

377 **CONCLUSION**

378 The validity of the outcome of any research depends, to some extent, on the
379 extent of adequacy of the sample used in the course of the research. [15] states that
380 the size of sampling error indicates the reliability or precision of the research.
381 According to him, as the sample size increases, the error decreases and hence larger
382 samples are considered more reliable and more representative than smaller samples.

383 In view of the fact that representative samples invigorate and accelerate the
384 process of research, there is need for researchers' training in the special area of
385 "sample representativeness", According to [5], such training could lead to improved
386 research and accelerated technological innovation.

387 In this paper, some suggestions are made regarding how representative
388 samples can be carved out from designated universe or populations. If the
389 suggestions are strongly adhered to by researchers, random fluctuations or sampling
390 errors will be minimized. The lower the sample errors, the more representative a
391 sample becomes.
