3 **AN EXAMINATION OF REPRESENTATIVE**
4 **SAMPLE IN DATA-BASED RESEARCH**
5

6 **ABSTRACT**

7 *The output of any research work depends, to a reasonable extent, on the adequacy of the*
8 *sample from which data are obtained for the research. A sample is adequate when it is*
9 *representative of the population or when it possesses the characteristics that are typical of the*
10 *population from which it is drawn. The focus of this paper is on how researchers can select*
11 *samples that are really representatives. Descriptive method was utilized in the writing of the*
12 *paper. Attempts are made, in the paper, to describe the concepts of sample representativeness,*
13 *sampling methods and sampling error. Some suggestions are then made on measures to take*
14 *in carving out truly representative samples.*

15 **Keywords:** *Selection, Sample, Representative sample, Descriptive method,*
16 *sampling error.*

17
18 **INTRODUCTION**

19 Information Technology has dominated the world today and radical
20 technological change and fusion have changed the way work is organized and
21 performed [1]. To this end, frantic efforts are made to obtain relevant information on
22 different aspects of human life.

23 Managers are fond of making decisions on different areas of business management
24 in order to achieve organizational objectives. The decision making process requires
25 certain information that will provide essential clues to certain issues. The
26 information so needed could be derived from hundreds or thousands of prospective
27 respondents who could be consumers, suppliers, employees, scholars or
28 government officials. As a result of the largeness of the population being dealt with,
29 a researcher may need to carve out just a fractional segment of the entire population
30 to ensure easy and timely collection of data. Herein lies the relevance of sampling.

31 It is one thing to create a sample out of a particular population; it is another
32 thing to ensure that the sample is large enough to represent the population. By
33 population, we mean the totality of items in an investigation [2]. In other words,
34 population is a collection of the individual items that are to be observed in a given
35 problem situation; the items could be living or non-living things.

36 A sample is a selected portion or subset of the population being investigated
37 [3]. The elements in the sample possess the same characteristics with the population
38 but the differences are in the size; that is, sample < population [4].

39 A quality control manager may decide to take a few cocoa beans, say 50, from a

40 bag of cocoa to investigate the quality level of the content of the bag. The thinking of
41 the quality control manager is that by examining 50 out of the entire cocoa beans in
42 the bag, he will get a fair notion of the quality of the entire population cocoa beans
43 inside the bag.

44 The objective of this paper is to find answers to the following questions:

- 45 i. What are the different methods of creating samples?
- 46 ii. What should be done to ensure selection of a truly representative sample?
- 47 iii. How can sampling errors be reduced?

48 In view of the nature of this study, descriptive method was used in writing, the
49 paper.

50 Towards this end, efforts were made to describe sampling methods, sample
51 representativeness and sampling error.

52

53 **SAMPLING METHODS**

54 Sampling is the process of taking any part of a population or universe as
55 representative of that population or universe [5]. Another way of saying the
56 foregoing is that sampling is a means of estimating population parameters from only
57 a few items. The process takes place especially when the population being studied is
58 a large one such that it becomes impossible or costly to investigate each item in it
59 (population). What could be done in that situation is to select a few elements from
60 the whole of materials being investigated and then make a generalization about the
61 population [6]. The method by which sample was drawn determines, to a reasonable
62 degree, the extent to which generalizations about the population can be made [7].
63 The sampling method so used determines the representativeness of the sample in
64 relation to the population.

65

66 Sampling methods can be categorized into two main classes namely,
67 probability sampling techniques and non-probability sampling techniques.

68

69 **1. PROBABILITY SAMPLING METHODS:**

70 These are sampling techniques for which we can determine the chance of
71 drawing each member of the population to form a sample. The method describes a
72 situation in which each item within the population has equal chance of being chosen
73 to form a sample [8]. Thus, there is no bias in the selection of sample members. One
74 other major advantage of this set of sampling methods is that it is easy to measure
75 the sampling error and interpret sampling results. As a result of these favourable
76 features, conclusions reached by studying a particular sample are considered
77 generalizable to that population or other similar populations. Some of the
78 probability sampling methods are:

79

80 **Simple Random Sampling:** This sampling method Involves selecting a few elements
81 from a total population in such a way that each member of the population has an

82 equal chance of being selected. Thus, a sample drawn at random is unbiased in the
83 sense that no member of the population has any more chance of being selected than
84 any other member [9].

85

86 One means of carving out a sample from the entire population is to name or number
87 each item in the population. Next, each name or number is cut into a small slip and
88 squeezed and then placed in a container. The investigator puts his hand into the
89 container to pick the number of slips required to obtain the required size of the
90 sample.

91

92 The selection procedure described above may not be possible in a situation where
93 the studied population is very large. For instance, taking a random sample of the
94 population of Lagos State, a table of random numbers, an example of which is
95 shown in Table 1, becomes useful. The computer is often used to accomplish the
96 selection process at this level.

117

118

119 **Stratified Sampling:** According to [10], stratified sampling method is best suited to
 120 populations that have different sets of groups within them. In other words, the
 121 sampling method is mostly used when dealing with heterogeneous populations. For
 122 instance, if a researcher wants to collect relevant data on a topic that says “Life after
 123 death” from a set of people, the best sampling method to use is stratified sampling.
 124 The reason being that the population being sampled will comprise people of
 125 different religious beliefs who are bound to have different opinions on the subject
 126 matter. In this case, the heterogeneous population will have to be divided into three
 127 homogeneous groups or strata as follows; Christians, Muslims and Traditional
 128 believers.

129
 130 Stratified sampling is of two types namely, proportionate stratified random
 131 sampling (PSRS) and disproportionate stratified random sampling (DSRS) [7]. In
 132 PSRS, the population is first stratified in terms of one or more variables of interest to
 133 the researcher. Elements are drawn randomly from each stratum in such a way that
 134 the relative proportions of the strata in the resultant sample are the same as exist in
 135 the parent population. This is saying that the relative contribution of each stratum in
 136 the population is exactly its relative contribution in the sample.

137
 138 **Proportionate stratified random sample** ensures greater representativeness
 139 of the sample relative to the population and guarantees that minority constituents of
 140 the population are represented in the sample [7] and [3]. Table 2 below illustrates
 141 PSRS with a population of 1220 entrepreneurs.

142
 143 **Table 2:** Distribution of a population of 1220 entrepreneurs according to
 144 categories/sizes with the proportionate stratified random sample.
 145

Entrepreneurs	Small Scale	Medium Scale	Large Scale	Total
Population Size	549	427	244	1220
Proportion	0.45	0.35	0.20	1.00
Sample size	110	85	49	244

146
 147 In case of disproportionate stratified random sampling, the relative proportions of
 148 the strata in the sample do not correspond to their relative proportions in the
 149 population. Some strata may be under-represented or over-represented in the
 150 sample. Obviously, this sampling mode allows the researcher the freedom of
 151 weighting the various strata in any manner he considers fit. Though the method
 152 does not make for proper representativeness, [3] was of the opinion that the DSRS
 153 method is preferred where the researcher believes that there is likely to be great
 154 within-stratum variation in responses or if he has a particular interest in one or more
 155 strata.

156
 157 **Systematic Sampling:** It is also called quasi-random sampling. In this method, the
 158 first sample element is randomly chosen from numbers 1 through K and subsequent
 159 elements are chosen at every Kth interval [5]. K will be determined by the size of the
 160 sample required. For example, if the population of Texy University is 16,000 and a

161 list of all the students making up the population is available. If a sample of 200
162 students is to be taken, the selection of every 80th student will give the required
163 sample.

164

165 The value of K above is determined as follows.

166

$$167 \quad \frac{\text{Total population}}{\text{Required sample}} = \frac{N}{n}$$

168

169

170

Therefore,

$$k = \frac{16,000}{200}$$

171

$$= 80.$$

172

173 It must be noted that systematic sampling is used only when the list of all items in a
174 population is available as in the case of a class register. The question as to how to
175 determine the first element that will form the sample is answered by choosing a
176 number at random between 1 and 50.

177

178 **Cluster Sampling:** Cluster sampling is otherwise known as area sampling. It is
179 successive random sampling **units** or sets and subsets [11]. In selecting a sample
180 using this method, the population (or geographical area) is divided into units or
181 segments with well-spelt-out boundaries. A specified number of these units or a
182 section is drawn. All elements in the units or sections drawn now constitute the
183 sample.

184

185 Cluster sampling is used when it can be recognized that some populations are
186 distributed in clusters or groups of settlement and these clusters are to be used as
187 the basis for sampling [3].

188

189 Unlike stratified sampling, using cluster sampling does not require a list of
190 the elements in the population before sample can be drawn [12]. As long as these are
191 distinguished clusters or geographical locations, creating samples becomes feasible.

192

193

2. NON-PROBABILITY SAMPLING METHODS:

194

195 Non-probability sampling is non-scientific approach to sample formation [13]. It
196 is the process of getting samples from populations without following any statistical
197 rules. The researcher or investigator uses only his intuition to select sample members
198 is fraught with bias and partiality simply because each item in the population does
199 not have an equal chance of being selected. The ultimate consequence of this
200 abnormality is that it becomes difficult to measure the sampling error and to
201 interpret results. The following techniques are examples of non-probability sampling
methods:

202 **Judgmental Sampling:** This involves the use of the researcher's reasoning and
203 judgment to obtain a sample, what determines whether an item in the population
204 will be selected or not into the sample is the personal preference of the investigator.

205 Sampling here is influenced by the personal bias of the person or group of persons
206 selecting members for the sample. That is not to say, however, that judgment
207 sampling is a complete write-off. It is advantageous in the sense that it saves time as
208 the process does not require any listing or numbering of the population or random
209 number tables [9].

210 **Quota Sampling:** According to [7], this involves selecting those elements that have
211 specific characteristics of interest to the researcher and are accessible to him. This
212 type of sampling is used to ensure that specific elements will be included.

213 Evidently, quota sampling gives room for the researcher or investigator to include
214 any category of the population that is of particular interest to him. It is quicker,
215 easier and cheaper. It is disadvantageous in the sense that the resultant sample is
216 highly biased and thus, cannot be said to be representative [14].

217 **Convenience Sampling:** The major consideration of the researcher using this
218 sampling method is the ease of selecting the sample. The researcher makes no
219 attempt to bring in any element of randomness. He selects members of the sample in
220 a way that is convenient or easy for him.

221 As an illustration, a student of Adekunle Ajasin University, Akungba-Akoko,
222 Nigeria, researching on the topic "The problem of small-scale business entrepreneurs
223 in Ondo State" may decide to get the required sample of small-scale business
224 entrepreneurs from Ikare-Akoko and Owo. This is because the two towns are very
225 close to his institution of research and so, can easily or conveniently collect the
226 needed data from respondents in the two towns.

227 In fact, the researcher does not know how well a Convenient Sample will represent
228 Sample the population regarding the traits or mechanism under research. What
229 makes convenience sample so unpredictable is their vulnerability to severe hidden
230 biases [15].

231 Therefore, in convenience sampling, the individuals selected by the researcher may
232 not be applicable to the research problem.

233 Hence, there is a rise of collecting poor quality data due to poor outcomes such as,
234 difficulty to convince others to accept the findings or research based on poor
235 foundation [16].

236 **Snowball Sampling:** This method is often used to obtain samples in situations
237 where there is no adequate list which could be used as a sampling frame [9].
238 Towards this end, the researcher contacts a member of the population of interest or
239 identifies a group of respondents who possess the traits desired for the research

240 work [3]. This set of people will in turn, identify another set of people suitable for the
241 research work. This chain continues.

242

243

244 SAMPLING ERROR

245 Sampling error simply means deviation from population values. It is the difference
246 between the result obtained from a sample and the result which would have been
247 obtained from the population. This type of error often occurs when the complete
248 survey of the population is not carried out, but a sample is taken for estimating the
249 characteristics of the population [17]

250 When the entire population is considered no sampling error occurs. The occurrence
251 of sampling error when a sample is carved out of a population depends on the size
252 of the sample relative to the population. As shown in Figure 1, the smaller the
253 sample the larger the error, and the larger the sample the smaller the error.

276

277

278

279

280

281

271 Size of Sample
272 Figure 1: Sample size vis-à-vis sampling error

274 It is possible to measure the sampling error [8]. The error is measured by the
275 standard error of the statistics in terms of probability under the normal curve. The
276 result of the measurement indicates the precision of the estimates of the population
277 based on the sample study [9].

278

279 Sampling error is derived by calculating the standard error of sample mean. It is the
280 standard deviation of the sampling distribution of sample means [6]. It is denoted by
281 δx and is given by

282
$$\delta x = \frac{\delta}{\sqrt{n}}$$

283 δ = Standard deviation of the population

284 n = Sample size

285

286 It is often advocated that large samples should be used. They are advocated

287 in order to give the principle of randomization a chance to work [5].

288

289 **SAMPLE AND REPRESENTATIVENESS**

290 The word “representative” means to be typical of a population; that is, to

291 exemplify the characteristics of the population. The fact that a segment of a

292 population is taken as representative of that population does not mean that the sample,

293 so taken, is representative. For example, a researcher investigating a banking habit in

294 First Bank Plc, may decide to draw his sample from two branches of First Bank in

295 Lagos, Nigeria, thereby assuming that the two branches represent the total

296 population of the bank’s branches. That sample selection may be wrong as data and

297 opinions collected from the two branches may not be representative of what actually

298 happens in the entire First Bank Plc network. That goes to show that too small

299 samples are not good enough as they tend not to represent the characteristics of the

300 population. This will eventually result in getting results that are likely to be lacking

301 in validity.

302 In research, a “representative sample” means that the sample has

303 approximately the characteristics of the population relevant to the research in

304 question [5]. If sex and socio-economic class are characteristics relevant to the

305 research, a representative sample will have approximately the same proportions of

306 men and women and middle class and working class individuals as the population.

307

308 The question as to how large a sample must be to be adequate or to be truly

309 representative is not a simple one. Each situation presents its own problems. If the

310 phenomena under study are homogenous, a small sample is sufficient. If units under

311 study are variable, a much larger sample is needed. The greater the variability of the

312 phenomena, the greater the difficulty of obtaining an adequate sample. But that is

313 not to say that using very large samples is always wise. Making use of samples that

314 are too large amounts to waste resources - money, time and energy.

315

316 In order to obtain a representative sample, the following points need to be

317 borne in mind by the researcher.

- 318
- 319 1. There is need for care and precision on the part of the researcher. He must
 - 320 take care to see that the sample drawn from the population is not biased.
 - 321 Towards this end, it is preferable to use probability sampling methods in
 - 322 selecting sample members since such a procedure guarantees that every
 - 323 population element has equal chance of being selected.
 - 324
 - 325 2. The population being investigated must be properly defined. It should be

326 defined in terms of four things namely, the element, sample unit, extent and
327 time [18]. For instance, a survey of consumers might specify a relevant
328 population as follows:
329

330

331

332	3. Elements	:	Male
333	Sampling Unit	:	27-35 years
334	Extent	:	Kaduna State, Nigeria
335	Time	:	As at 30 th October, 2016

336

337 In the alternative, the population for a study designed to measure buyers' reaction to
338 a new pharmaceutical item may be the following:

339	Element	:	Pharmacists
340	Sampling Unit	:	Pharmaceutical companies buying over 341 ₦5 million worth of item per year.
342	Extent	:	Enugu State, Nigeria
343	Time	:	Year 2014

344

345 The essence of defining studied population properly is to ensure that whatever data
346 are obtained from the selected sample meet the researcher's expectation in terms of
347 data currency, respondents/interviewer's level of experience and
348 geographical/professional coverage.

349

350 4. The usual thing to do after identifying a population is to obtain a complete
351 and current list of all elements in the population. Nonetheless, in order to get
352 a representative sample, the researcher should avoid drawing a sample by
353 preparing an alphabetical list and proceeding down the list until he has
354 included a sufficient number in the sample. Some letters of the alphabet
355 include more names from certain groups than others, and this may produce
356 bias in the sample on the basis of name alone.

356

357 5. The idea of allowing interviewers to select interviewees who are like
358 themselves should be discouraged. Such a habit results in a biased sample.
359 For example, if interviewers or researchers are members of a particular
360 religion, they will likely select many interviewees from the same religion and
361 include just a few individuals from other religions. Samples obtained through
362 such an awkward procedure will produce opinions and data that are not
363 representative of the entire population [14].

363

364 6. [3], in his own contribution, opines that samples must be adequate enough to
365 generate generalizable result of findings. There is need for researchers or
366 investigators to ensure that the elements that make up a particular sample are
367 those that possess the features that are typical of the entire population.

367

368 CONCLUSION

369

370 The validity of the outcome of any research depends, to some extent, on the
371 extent of adequacy of the sample used in the course of the research. [13] states that

371 the size of sampling error indicates the reliability or precision of the research.
372 According to him, as the sample size increases, the error decreases and hence larger
373 samples are considered more reliable and more representative than smaller samples.

374 In view of the fact that representative samples invigorate and accelerate the
375 process of research, there is need for researchers' training in the special area of
376 "sample representativeness", According to [19], such training could lead to
377 improved research and accelerated technological innovation.

378 In this paper, some suggestions are made regarding how representative
379 samples can be carved out from designated universe or populations. If the
380 suggestions are strongly adhered to by researchers, random fluctuations or sampling
381 errors will be minimized. The lower the sample errors, the more representative a
382 sample becomes.
