

Original Research Article

Spatial Epidemiology of Road Traffic Crashes and Mortality in Nigeria, 2007-2015

Abstract

Background: Road traffic accidents (RTA) are an important public health problem with considerable morbidity mortality and disability especially in low income countries. Spatial analysis tool has been used in the study of RTA in high income countries while very few studies have been carried out in Africa including Nigeria. This study was therefore conducted to explore the epidemiology of road traffic accidents in Nigeria using spatial analytical tools.

Methods: The study is an ecological study which utilizes secondary data on road traffic accidents and mortality between 2007 and 2015 from the Federal Road Safety Corp in Nigeria. The 36 states and Federal Capital Territory were used as the unit of geographical analysis. The global Moran's I and Local Moran's I (LISA) test were used to measure spatial autocorrelation and significant levels were taken at $p < 0.05$.

Results: A total of 83,548 road traffic accidents and 76,822 deaths were reported in Nigeria from 2007-2015. The total road crashes in 2007 was 5.7/100,000 population and this increased gradually to a peak of 8.7/100,000 population in 2009 and this declined to 2.9/100,000 in 2011 and to another peak of 7.8/100,000 in 2011. However, the peak year for deaths as a result of road traffic crashes was in 2010. On the average, Federal Capital Territory had the highest frequency of road crashes while Kano state had the highest frequency of deaths associated with road crashes. Nasarawa state and the Federal Capital Territory were identified as hotspots for road traffic crashes and mortality associated with road traffic crashes in the country.

Conclusion: The study found a decline of RTA over the years under study. There was significant clustering of RTA occurrence and death in the federal capital territory and Nasarawa state. The

findings can provide evidence based information to policy makers to deploy scarce resources to hot spot states in order to mitigate the occurrence and mortality as a result of RTA in the country

Introduction

Road traffic accidents are an important public health problem with considerable morbidity mortality and disability especially in low income countries. The World Health Organization estimates that about 1.25 million people die each year as a result of road traffic crashes and about 90% of these deaths occur in low - and middle - income countries, though these countries have approximately half of the world's vehicles^[1]. Apart from deaths, it is estimated that about 20-50 million more people suffer non-fatal injuries, which has resulted in permanent disabilities^[1].

In comparison to the high income countries, road traffic deaths are more than double in low and middle-income countries. The African region has the highest road traffic deaths in the world and the region also has the highest pedestrian and cyclist deaths of all road traffic deaths partly as a result of economic development which led to an increase in the number of vehicles on the road and the fact that the road infrastructure were not improved to accommodate the increase coupled with the low level of the implementation of safety measures to protect road users^[2]. . The consequences of road traffic injuries includes considerable economic losses as a result of cost of treatment, reduced or lost productivity as a result of death, injury or disability or due to family members who take time off work to care for their injured loved ones^[3]. In 2013, 90% of disability adjusted life years (DALYs) lost from road traffic injuries occurred in low- and middle-income countries^[4].

There has been a strong international response to combat the menace of road transport accidents. The United Nations General Assembly declared 2011–2020 as the Decade of Action for Road Safety in an attempt to galvanise international support to improving safety of roads and combat

road traffic crashes^[5]. In addition, a new road safety target was set as part of the Sustainable Development Goals which considers halving the global number of deaths and injuries from road traffic crashes by 2020. The achievement of these goals will require concerted efforts from all stakeholders especially in sub-Saharan Africa.

One of the tools that can assist governments in sub-Saharan African to achieve the stated sustainable development goals is to combine spatial data (data on geographic units) to the increasingly available data on road traffic accidents (RTA). The use of spatial analysis in the study of RTA has the capability to identify, locate and characterize the patterns of road traffic accidents, enable the visual analysis of hot spots and the identification of contributory factors with a view to determine targeted interventions which are necessary to prevent or mitigate future occurrence of road traffic accidents. Spatial analysis tool has been used in the study of RTA in high income countries while very few studies have been carried out in Africa including Nigeria. Some studies have applied spatial analytic tools to identify hot spots for road traffic accidents and deaths in Nigeria but this has been limited to only one state or at the regional level ^[6-10] and there is no study to our knowledge that have either applied spatial analytic tool to the entire country or use R statistical software to conduct spatial analysis. This study was therefore conducted to explore the epidemiology of road traffic accidents in Nigeria using spatial analytical tools.

Methods

Study design

The study was an ecological study of road traffic accidents in Nigeria between 2007 and 2015. The data for road traffic accidents at the national and sub-national level was obtained from annual report from 2007-2015 by the Federal Road Safety Corps in Nigeria^[11]. Nigeria is the

largest country in West Africa with a projected population of about 170 million people^[12].. It has 36 independent states and a Federal Capital Territory (FCT) which are grouped into six geopolitical regions. The 36 states and the FCT were used as the unit of geographical analysis. The shape file of the country at the first administrative level (36 states and the FCT) was obtained online from the administrative areas RDM (www.rgdam.org)

Spatial exploration

The 36 states and FCT were used as the unit of geographical analysis. The global Moran's I index was used to estimate the strength of the global spatial autocorrelation of the average road traffic accident rate per 100,000 populations in this study. The Global Moran's I share many similarities with Pearson's correlation coefficient and like a correlation coefficient, the values of Moran's I range from -1 to +1. A Moran I of +1 suggests a strong positive autocorrelation while a value of -1 suggests a strong negative spatial autocorrelation. The usefulness of Moran's I lie in its simplicity but its major limitations is that it tends to average local variations in the strength of spatial autocorrelation^[13]. The global autocorrelation is a single measure that was used to assess the spatial autocorrelation of average road traffic accident rate per 100,000 populations in the country as a whole.

The global Moran I is expressed by the formula^[14].

$$I = \frac{N}{\sum_i \sum_j w_{ij}} \frac{\sum_i \sum_j w_{ij} (X_i - \bar{X})(X_j - \bar{X})}{\sum_i (X_i - \bar{X})^2} \dots\dots\dots(1)$$

Where N is the number of spatial units i.e. the 36 states and the Federal Capital territory indexed by i and j; X is the variable of interest (average leprosy case detection rate), $\bar{X}$ is the mean of X; and W_{ij} is an element of a matrix of spatial weights. In this study, we used a first order adjusted connectivity matrix, in which region i is considered neighbour of region j, if they share a

common boundary. W_{ij} is zero (0) everywhere except for a contiguous location i and j where it takes the value of 1.

The Local spatial autocorrelation (LISA) developed by Luc Anselin has become the standard tool to examine local spatial autocorrelation. This can be seen as the local equivalent of Moran's I . The LISA is particularly useful in situations where there are pockets of areas showing homogeneous values that do not follow the global trend of observations. This can lead to the identification of hot-spots where road traffic accident rate is pronounced across localities. It is expressed as ^[15].

$$I_i = z_i \sum_j \omega_{ij} z_j \dots\dots\dots(2)$$

Where z_i is the original variable x_i (road traffic accident rate per 100,000 populations) in standardized form and ω_{ij} is the spatial weight as described above for global autocorrelation.

A choropleth thematic map was used to visualise possible clustering and the states with significant spatial autocorrelations were identified by mapping the P -value of the Local Moran's I statistics. The false discovery rate (FDR) method by Benjamin and Hochberg's was used for the adjustment of the local Moran's I p values ^[14]. A final choropleth map of local Moran's FDR-adjusted p values was produced and a P -value of ≤ 0.05 was regarded as statistically significant.

The analysis of the data was carried out in R statistical package version 3.2.3

Ethical Consideration: Ethical clearance was not sought for this study because the study was based on road traffic accident data freely available at the Federal Road Safety Corp website in Nigeria with no personal identifiers.

Results

A total of 83,548 road traffic accidents and 76,822 deaths were reported in Nigeria from 2007-2015. The road traffic crashes rose from 8477 in 2007 to 13,684 in 2009 after which there was a

gradual decline to 4765 in 2011. A gradual rise was observed to 13,583 in 2013. Similarly the mortality associated with the road traffic crashes rose from 4673 in 2007 to a peak of 22,160 in 2010 after which there was a gradual decline to 4372 in 2011. Thereafter there was a steady increase to 6544 was observed as shown in figure 1. Similarly, the total road crashes per 100,000 population was 5.7/100,000 population in 2007 and this increased gradually to a peak of 8.7/100,000 population in 2009 and this declined to 2.9/100,000 in 2011 and to another peak of 7.8/100,000 in 2011. In contrast the peak year for deaths as a result of road traffic crashes was in 2010 as shown in figure 2. Figure presents the distribution of road traffic crashes per 100,000 population among the 36 states and the federal capital territory. Eight states had road traffic crashes above 7.6/100,000 population. The states are Ogun, Osun, Kwara, Niger, Kaduna, Nasarawa, Edo and the Federal Capital Territory as shown in figure 3. The states with the high mortality rate associated with road traffic crashes above 7.7/100,000 population were Ogun, Ondo, Edo, Kwara, Nasarawa, Benue, Gombe and the Federal Capital Territory as shown in figure 4. Nasarawa state and the Federal Capital Territory were identified as hotspots for road traffic crashes and mortality associated with road traffic crashes in the country. as shown in figure 5 and 6.

Table 2 shows the trend of road traffic accidents reported by the 36 states and the federal capital territory (FCT) from 2007-2015. On the average the Federal Capital Territory had the highest frequency (844.9) of road traffic crashes while Sokoto state had the lowest frequency (89.6). On the contrary Kano state had the highest frequency of deaths (535.8) due to road traffic crashes while Bayelsa state had the lowest frequency of mortality due to road traffic accidents during the period of under review.

Discussion

Spatial analysis is a tool that has the capability to identify, locate and characterize the patterns of road traffic accidents, enable the visual analysis of hot spots and the identification of contributory factors with a view to determine targeted actions necessary to prevent or mitigate the future occurrence of road traffic accidents^[16-17].

The study demonstrates a general decline in the rate of road traffic accidents and associated mortality in the country compared with an all-time high of 716.57/100,000 reported in 1990^[18]. In spite of this decline at the national level, there exist wide variations at the subnational level which showed pockets of high rate of road traffic crashes and associated mortality in some states. The study identified significant clustering in two contiguous locations namely the Federal Capital Territory and Nasarawa state. The FCT is a gateway city between the southern and the northern part of the country with major highways namely Abuja-Lokoja, Abuja-Akwanga, Abuja-Jos Abuja-Suleja and Abuja Kaduna highways. These highways are characterized by a high volume of traffic, gridlocks and excessive speed by commuters. As the political capital of the country, there is a growing migration of individuals from the neighbouring states and from all over the country which has resulted in increased population density and vehicular movement in the city. Some studies have shown an association between economic development of cities and road traffic accidents^[9-19]. A study in FCT identified some factors that may be responsible for the RTA. The major factor found was the non-compliance with traffic rules by drivers. Some studies have suggested that better road found in urban centres like the FCT have higher rates of accident and mortality largely because of drivers non-compliance with speed limits^[8,20]. Other studies have also identified poor road infrastructure and maintenance which result in pot-holes which are 'death traps' to motorist^[17,21,22]. Similarly, the FCT and Nasarawa state were also identified as

162 hot spots for mortality associated with RTA. The increased mortality could be as a result of poor
163 medical emergency services^[23].

164 **Study limitation**

165 The major limitation is that the data utilized from this study was from government sources which
166 may not adequately represent the true burden of RTA in the country. The lack of reliably
167 information especially mortality associated with RTA may be as a result of lack of active
168 surveillance and follow up to report the outcome of road crashes. There is need for interagency
169 collaboration to improve the data system on RTA in the country.

170 **Conclusion**

171 The study found a decline of RTA over the years under study. There was significant clustering of
172 RTA occurrence and death in the federal capital territory and Nasarawa state. The findings can
173 provide evidence based information to policy makers to deploy scarce resources to hot spot states
174 in order to mitigate the occurrence and mortality as a result of RTA in the country.
