Remittance: Consumed Or Invested? A Macro-Model of the Nigerian Economy

ABSTRACT (ARIAL, BOLD, 11 FONT, LEFT ALIGNED, CAPS)

ABSTRACT

The increasing trend in remittance receipts, especially to developing countries has increased the opportunities for external sources of finance for investment and growth. However, while some literatures suggest that remittance matter for growth through investment, others contend that the relationship between remittance and growth depends on its end use. Given an import-dependent economy like Nigeria, it is necessary to examine the end-use of remittance – whether it is consumed or invested. Employing a quarterly time series data from 1986 to 2014 in a Keynesian dynamic macroeconomic framework, the results show that remittance significantly induces consumption expenditure, but depresses investment expenditure and output growth in Nigeria. Specifically, when 1% remittance is received in Nigeria, it significantly induces consumption spending by 2.1% but insignificantly depresses investment spending and growth by 6.4% and 03% respectively, ceteris paribus.

Keywords: consumption expenditure, growth, investment expenditure, Nigerian economy, remittances

1. INTRODUCTION

The Nigerian nation is facing the problem of increasing number of her skilled and unskilled labour migrating to other countries with the attendant brain drain. This negative trend is yielding positive fruits in form of remittance inflow. Remittance has become the second largest source of external finance next to oil, exceeding Official Development Assistance (ODA) since 1993 both in value and as percent of GDP, and surpassing FDI inflow since 1999 save for 2001, 2002 and 2003. Remittance was approximately 8 times the value of portfolio inflow for the same period and more than 30% of total export earnings in the most recent 12 year period. At regional level, remittance inflow into Nigeria represents about 50% of total remittance inflow to Sub-Saharan Africa (SSA) and approximately 77% of total inflow to West African countries.

Three factors – pull, push, and advancement in technology – may be advanced for this sudden upsurge in remittance inflow into developing countries including Nigeria (Lin, 2011[1]; Guiliano and Ruiz-Arranz, 2005[2]). First, the developed and industrialized nations' demand for labour supported by the huge wage differences between developed and developing nations is the main pull factors that attract migrants to developed countries. Second, increasing rate of unemployment, falling economic prospects, volatile political environment, under-developed agriculture in both rural and urban areas, under-developed and inadequate infrastructure, and weak corporate governance are some of the factors that push migrants out to the outside world (Lin, 2011[1]). Third, according to Guiliano and Ruiz-Arranz (2005[2]), the technological advancement that has allowed for quicker, cheaper and easier international transfers between individuals and among countries and the attendant reduction in transaction costs have led to the current upsurge.

Remittance inflow is important because it affects growth in the recipient developing economies through savings and investment. Its potentials to scale up domestic consumption have short run effects on aggregate demand and output (Solimano, 2003[3]). Finally, the balance of payment position of a country is determined by remittance inflow as it constitutes a major portion of a country's foreign exchange reserve. Available data support the upward trend in remittance inflow into Nigeria (figure 1). For instance, in absolute value and as proportion of GDP remittance inflow into Nigeria was \$0.7 (₦0.5) million or 0.01% in 1970. It rose to \$804 (₦65,365.2) million or 2.91% in 1995, \$1.4 (₦142.4) billion or 3.87% in 2000, \$14.6 (₦1,899.6) billion or 13.04% in 2005, and \$23.0 (₦3,645.9) billion or 9.04% of GDP in 2012 World Development Indicator (WDI), 2012[4]).

Despite the upward trend, the nature and magnitude of the economic implications of remittances into Nigeria is not clear, especially given the import-dependent-consuming peculiarity of the country. A cursory look at the WDI (2012[4]) import content of foreign trade reveals that in 1970 total import was \$1.4 billion (₦84.0 million), but rose to \$6.9 (₦561.0) billion in 1995. By 2005, import figure had climbed to \$21.4 billion (₦2.2 trillion), and rose further to \$88.4 billion (₦13.9 trillion) in 2011. As a ratio of GDP it was 11.2%, 24.0%, 19.1%, and 36.0% in the years 1970, 1995, 2005, and 2011 respectively (WDI, 2012[4]). On its part, the outcome of gross fixed capital formation both as value and proportion of GDP

during the period was rather mixed as depicted by WDI (2012[4]) data. For example, in 1990, 1995, 2005, and 2011 it was $4.4 (₦35.4) billion, $2.0 (₦162.6) billion, $6.1 (₦620.4) billion, and $25.3 billion (₦3,802.6 trillion) respectively. However, as ratio of GDP it was 14.3%, 7.1%, 5.5%, and 10.3% respectively. The questions however, without bias to existing studies (see for instance, Balde, 2010[5]; Faini, 2002[6]; Abeng, 2011[7]; Ukeje and Obiechina, 2013[8]) which show evidence that remittance inflow promote investment and hence growth are whether this huge remittance inflow actually scale up investment and consumption levels and hence create economic opportunities in recipient economies. Do available data on gross fixed capital formation on Sub-Saharan Africa (SSA) and Nigeria in particular support these findings; or is it that remittance inflow has savings-inducing potentials that has not yet been harnessed? Aware that remittance is essentially unrestricted private financial flows capable of financing investment and consumption, the study attempts to answer the question about the use of remittance. This stems from the fact that the use of remittance determines its macroeconomic effect. Previous studies dwelt on impact analysis of remittance (see for instance Ukeje and Obiechina, 2013[8]; Balde, 2010[5]). In this context, the study takes as a point of departure, the effect of the use of remittance on three macroeconomic variables – consumption, and investment, and growth – in Nigeria in the period 1986Q1 to 2014Q4. Structurally, the rest of the work is organised as follows: section 2 reviews relevant empirical literature and trends some important variables used for the study, section 3 discusses the methodology, section 4 presents and discusses the empirical results while section 5 presents the conclusion.

1.2 Related Theoretical and Empirical Literature

Studies in economic literature suggest conflicting relationship between remittance and growth. For instance, while Connell and Conway (2000)[9] contend that remittance has growth-inducing impact on investment, poverty alleviation, growth and development, studies such as Robert (2004)[10], Robert (2006)[11] argue that remittance does not contribute to economic growth and development. For Burnside and Dollar (2002)[12], Bjuggren, Dzansi, and Shukur (2010)[13], the impact of remittance on the growth of remitters' home economy can be either way, that is, it is conditional on its end use – whether it is consumed, saved, or invested. If it is invested, it is likely to have growth-promoting impact on the economy. Commenting in favour of its growth-inducing impact, Barajas, Chami, Fullenkamp, Gapen, and Montie (2009)[14] using growth accounting framework posit that remittance directly finance increase in capital accumulation in recipient economies compared to what would have been the case if such economies resort only to domestic sources of finance for investment. Mishra (2005)[15], Parajuli (2010)[16], World Bank (WB) (2006)[17], Lucas (2005)[18], Connell and Conway (2000)[9], and Ziesemer (2010)[19] all argue that remittances impact positively on investment. Specifically, Parajuli, Ziesemer, Connell and Conway add that remittance may promote investment in human and physical capital – education, housing and small business. WB argues that remittance raises investment and growth, especially in countries with highly skilled labour, strong institution and good policy environment.

However, Roberts (2004)[11] argue that by reducing the labour and saving efforts of recipient families, remittance impacts negatively on economic growth and development (moral hazard problem). Remittance may also hurt economic growth when the traded goods sector of recipient economy becomes the source of significant positive externalities that promote the productive capacity of other sectors. If this condition is satisfied, remittance may give rise to a Dutch disease effect to the extent that its inflow may cause the economy's real exchange rate to appreciate (Neupane, 2011)[20]. Finally, if remittance is disguised as capital flows (recipients investing on behalf of the migrant remitter) and the receiver is less skilled in investing, deficiency in investment is promoted to the extent that the unskilled investor may choose unprofitable investment and hence hurt future investment decisions from the remitter.

On the other hand, if consumed, remittance may hurt or have no impact on growth, especially in an import demand economy. For instance, if remittance is perceived to be permanent, they will tend to be consumed in their entirety and therefore will not affect aggregate investment. Similarly, the consumption impact of remittance on labour productivity depends on the living standard of remitters' family. If the standard of living of recipient family was sufficiently high to the extent that its basic needs are adequately met prior to the receipt of remittance, then the labour productivity effect of remittance disappears for that family as additional receipts from remittance may simply be consumed.

Arguing in favour of this theory, Durand, Parrado and Massey (1996)[21] contend that remittance receipts lead to an excessive consumption, especially on imported goods or unproductive residential investment such as house, jewellery and land. Paine (1974)[22] hypothesize that remittance increase the propensity to import since remitters families' taste and preferences for foreign goods and living standards have increased, especially after the return of migrant worker to their home. Azad (2005)[23] consider remittance as a major source of foreign exchange used to pay import liabilities in labour exporting economies. Arguing further, Lipton (1980)[24] writes that about 90% or more of remittance receipts are spent on daily-needs related consumption like food, clothing, house rent, etc. Massey, et al (1987)[25] report that between 68(%) to 86% of remittance sent to Mexico are spend on consumption. Rempel and Lobdell (1978)[26] posit that remittance is mainly devoted to daily consumption requirements.

Remittance, if saved has the potential to reduce the credit constraints to recipient households and promote entrepreneurship (Woodruff and Zenteno, 2002[27]; Funkhouser, 1995[28]). Stressing on the relationship between remittance and saving, Roberts (2006)[11] and Adams (2007)[29] add that remittance improves the propensity to save by households which ultimately increases the loanable funds of deposit money banks and hence its ability to expand credit to the private sector, increase investment potentials and this is expected to promote growth.

The end use of remittances may also be determined by the policy environment and institutional arrangements of the recipient country. By differentiating between countries with corruption level above median with those below median, Ratha (2003)[30] posit that corruption could have negative effect on the end use of remittances. Stark, et al (1988)[31] note that the income distribution policy of recipient country strongly determines the expected effects of remittances on her poverty and inequalities reduction.

1.2.1 Empirical Studies for Nigeria

Many researchers have investigated the end use of remittance in Nigeria and gave varying conclusions. While majority of the studies examine the importance of remittance on economic growth, others acknowledge that remittance affect growth through its impact on savings and investment.

Omobitan (2012)[32] in analysing the determinants of international migrants' remittances flow into Nigeria for the period 1977-2010, and employing Engle Granger two stage long run relationship found that there exist significant co-integration relationship between remittances and gross domestic product. The author recommends that more remittance inflows can be improved through official channels with the maintenance of macroeconomic and financial stability.

Ukeje and Obiechinna (2013)[8] in their study on Workers' Remittances–Economic Growth nexus in Nigeria using an error correction model for the period 1970-2010 found significant and positive impacts of remittances on growth in the long run. The duo equally report that in the short run, the lagged value of workers' remittances is significant, appropriately

UNDER PEER REVIEW

signed and impacts positively on economic growth. The study recommend the provision of adequate infrastructure for attracting more remittance inflows into the economy through formal financial sector channel while adopting measures to encourage the recipients to channel such into productive sector or through domestic savings that would boost investment and economic growth.

Agu (2009)[33] in his study on the relationship between remittance and the macro economy in Nigeria using a four-sector medium scale macro model found a weak link between remittances and the real sector and components of aggregate demand. He posited that the existence of leakages of remittance proceeds through consumption of imported goods could be responsible for the weak nexus.

Oduh and Urama (2012)[34] investigated whether the end-use of remittances will be poverty-reducing as well as growth-financing in an import-dependent economy like Nigeria. Using macro-econometric model with six behavioural equations and six identities to estimate and simulate the effects of remittances inflow on aggregate demand in Nigeria, the simulation result shows that the much touted poverty-reducing effect of remittances is non-growth-financing for import-dependent country like Nigeria. The authors blamed the results on the negative impact of imports on the current account balance despite remittance positive effects on private consumption and investment.

Ogbonna, et al (2014)[35] examined the linkages between remittance inflow and private domestic investment in Nigeria. Using a time series data from 1970-2012 and following Guiliano and Ruiz-Aranz (2005)[2] framework, OLS estimate was applied. The result indicates that remittance inflow is insignificantly negative in promoting domestic private investment, indicative that the quantum of remittance inflow into Nigeria has been hurting the country's domestic private investment in the long run. The authors recommend that Nigerian government should institute international and local initiatives and measures that would woo Nigerians in Diaspora to channel migrant transfers into investment at home to promote investment and hence economic growth.

Okodua (2013)[36] examines the private investment outcomes of workers' remittance flows to some selected Sub-Saharan African (SSA) countries using the system Generalized Method of Moments in a linear dynamic panel data model. A major finding is that remittance has a significant contemporaneous positive impact on private investment across the sampled countries over the study period. Okodua result suggests that remittance inflow to SSA occur as both financial and capital flows.

2. METHODOLOGY, MODEL AND DATA SOURCES

To evaluate the aggregate spending effects of remittance on domestic consumption, domestic investment, and the gross domestic product of the Nigerian economy, we reiterate the four uses of remittances as enunciated by Ratha, (2009)[29]. Ratha had posited that remittance receipts were spent for consumption, investment, health, and education. In this study, however, we collapse the four uses into two, mainly to suit the objectives of the study, and too, in line with NBS (2012)[37] data generating process which lumped 'health' and 'education' into non-food consumption. We consider simultaneous equation system as most appropriate to evaluate the impact of remittances on domestic investment, domestic consumption and aggregate expenditure in Nigeria economy in the period 1986-2013.

In line with the objective of the study which aims to explore whether remittance induces domestic investment, consumption and growth in Nigeria, the Keynesian dynamic macroeconomic framework is formulated to examine the aggregate spending effect of remittance on consumption, investment and national income. The three systems of behavioural equations are thus formulated:

Model 1

Theoretically, the positive determinants of consumption expenditure (CE) include, income (Y), and income in the previous year (Y_{t-1}), while savings deposit rate (SVG) is a negative determinant. Private Consumption expenditure is made up of food, and non food (including services) items. Literature is replete with studies which posit that remittance receipts are spent on daily-needs related consumption like food, clothing, house rent, etc. Based on this, it is important to explore the relationship between remittance and private consumption expenditure in Nigeria. For our purpose and considering country-specific peculiarities, remittance (REM), and exchange rate (EXR) are also included. Hence, we model:

$CE = f(Y_t, Y_{t-1}, SVG_t, REM_t, EXR_t)$; $f'(Y_t) > 0$, $f'(Y_{t-1}) > 0$, $f'(SVG_t) < 0$, $f'(REM_t) > 0$, $f'(EXR_t) < 0$ ……. (1)

Model 2

In modeling the relationship between remittance and domestic investment, we recall that theoretically, domestic investment is positively determined by return on investment (profit) which itself is influenced by level of income and prime lending rate which is the cost of capital. Equivalently, current investment positively depends also on past investment which is also influenced by level of income. Hence, the relationship between remittance and gross domestic investment (INV_t) may be considered by establishing the relation among gross domestic product (Y_t), its one year lag (Y_{t-1}), remittance inflow (REM_t), and the prime lending rate of deposit money banks (INT_t). Symbolically:

$INV_t = f(Y_t, Y_{t-1}, INT_t, REM_t, EXR_t)$; $f'(Y_t) > 0$, $f'(Y_{t-1}) > 0$, $f'(INT_t) < 0$, $f'(REM_t) > 0$, $f'(EXR_t) < 0$ … . (2)

UNDER PEER REVIEW

Model 3

We now try to assess the degree of relation among remittance and gross domestic product in Nigeria. The traditional Keynesian aggregate demand function of a given economy assumes that consumption expenditure (CE_t), domestic investment (INV_t), government consumption (GE_t), export (XPT_t), and import (MPT_t), are responsible for the level of gross domestic product (Y_t).

For our purpose, we add remittances (REM_t) in the national income identity, so that:

$Y_t = f(CE_t, INV_t, GE_t, XPT_t, MPT_t, REM_t)$; $f'(CE_t) >0$, $f'(INV_t)>0$, $f'(GE_t)>0$, $f'(REM_t)>0$, $f'(XPT_t)>0$, $f'MPT_t<0$ (3)

For estimation purpose and to enable us interpret the results as percentages, the functional form and expected signs of the coefficients for equations 1-3 are expressed in their natural logarithm, hence:

$\ln CE_t = b_0+b_1\ln Y_t,+b_2\ln Y_{t-1}+b_3 SVG_t+b_4\ln REM_t+b_5\ln EXR_t+\varepsilon_t$ …… (4)

$\ln INV_t = a_0+a_1\ln Y_t+a_2\ln Y_{t-1}+a_3 INT_t+a_4\ln REM_t,+a_5\ln EXR_t+\mu_t$ …… (5)

$\ln Y_t = \beta_0+\beta_1\ln CE_t+ \beta_2\ln INV_t+\beta_3\ln GE_t+\beta_4\ln XPT_t,+\beta_5\ln MPT_t, \beta_6\ln REM_t +\gamma_t$ …… (6)

a_t, bt, βt, are parameters to be estimated, while ε_t, μ_t, γ_t, are stochastic error term for the respective equations.

Equations (7), (8), and (9) are with dynamic version of the long-run relationship (an error correction form) using ordinary least square regression models to allow for inclusion of long-run information:

$\ln\Delta CE_t = b_0+b_1\ln\Delta Y_t,+b_2\ln\Delta Y_{t-1}+b_3\Delta SVG_t+b_4\ln\Delta REM_t+b_5\ln\Delta EXR_t+\lambda ECM_{t-1}+\varepsilon_t$ ... (7)

$\ln\Delta INV_t = a_0+a_1\ln\Delta Y_t+a_2\ln\Delta Y_{t-1}+_{a3}\Delta INT_t+a_4\ln\Delta REM_t,+a_5\ln\Delta EXR_t+\Psi ECM_{t-1}+\mu_t$ ... (8)

$\ln\Delta Y_t = \beta_0+\beta_1\ln\Delta CE_t+\beta_2\ln\Delta INV_t+\beta_3\ln\Delta GE_t+\beta_4\ln\Delta XPT_t,+\beta_5\ln\Delta MPT_t,+\beta_6\ln\Delta REM_t+\psi ECM_{t-1}+\gamma_t$ ... (9)

Δ is the first difference operator, and λ, Ψ, ψ are the error correction coefficients, while the rest are as earlier defined

2.1 Data Sources

Our data are from three main sources, namely World Development Indicators (WDI), National Bureau of Statistics (NBS), and the Central Bank of Nigeria (CBN).

Data used for estimation in the models spanned 1986Q1 – 2014Q4. All the data sets were used as reported by their respective institutions. However, because data from WDI are reported in US dollar, prevailing naira exchange rate for each year was used to multiply to get the naira equivalent. This is for data consistency and because of the importance attached to data attributes of the affected datasets.

The choice of quarterly series was predicated principally on two crucial reasons. First, sufficient degrees of freedom relating to number of observations was critical, especially when estimating over-parameterised models. Second, because we are interested in investigating the behaviour of these variables after deregulation, annual data series from 1986 which marked the deregulation period might have insufficient degrees of freedom. Generating high frequency (quarterly) datasets from low frequency (annual) series was performed on E-views strictly on the software's econometric strength. In the study, real data sets were used for estimation and all the series, except interest rates were in logarithms, hence the results are interpreted as elasticities.

2.2 Estimation Techniques

Many types of techniques – ordinary least squares (OLS), autoregressive (AR), and maximum likelihood (ML) – exist for use in model estimation. One's choice of an estimation technique depends on the size/type of the model, availability of data and the recursive nature of the series. In our estimation, however, OLS was utilized. The choice was informed by the size of our model and the robustness of the technique.

To ascertain the quality of the variables in our model, we test for the order of integration of each time series using the Augmented Dickey-Fuller (ADF). This approach is apt since the ADF model accounts for the autocorrelation of the first differences of the series in a parametric way by guessing the value of additional nuisance parameters (Gujarati and Porter, 2009)[38]. Stationarity achieved, cointegration tests were conducted using Johansen and Juselius co-integration technique to determine whether or not there exist long run relationship among the series. The error correction model (ECM) technique was carried out for the various stochastic equations in the model to incorporate long run information.

EMPIRICAL RESULTS AND DISCUSSION

4.1 Time Series Properties of the Variables

Unit root and co-integration tests were performed on all the variables using the Augmented

Dickey-Fuller (ADF) and Johansen and Juselius co-integration technique respectively. For brevity, however, the results are not presented. For the unit root, all the variables are integrated (stationary) of order-one, that is I(1) except consumption and interest rate that are integrated at level form, that is I(0). In testing for co-integration employing both the Trace and Maximum Eigen-value statistics, the results indicate one co-integrating equation for trace and two for maximum eigen value for equation 4, one co-integrating equation each for equation 5, and three co-integration for equation 6. Consequently, error correction models (ECM) are used for all the models. The ECM variables utilized in the equations are: ECM1 (consumption-remittance) referred to as equation 7, ECM2 (investment-remittance) referred to as equation 8, and ECM (national income-remittance) referred to as equation 9.

4.2 Empirical Results

Table 1 shows the determinants of consumption, investment, and national income.

4.2.1 Consumption Expenditure-Remittance model

The results reveal that the positive determinants of consumption include: GDP, lagged GDP, remittances and exchange rate; while savings deposit rate affects consumption negatively (table 1a). Specifically, the results indicate that remittance significantly promote private consumption just as GDP, one quarter lagged GDP and exchange rate. Both GDP and its lagged coefficients met the a priori sign, that as national income (GDP) increases, private consumption expenditure rises ceteris paribus. This is in tandem with Keynesian theoretical formulation that income is a positive function of consumption. On its part, exchange rate coefficient is positive but insignificant indicative that for every 1% depreciation in exchange rate consumption increases by 4%.

The results also indicate that as remittance increases by 1%, private consumption expenditure which is made up of food and non food items significantly increases by 0.05%. The finding is indicative that in Nigeria, remittance raises the purchasing power of household recipients on food and non food items during the last two decades. Available data on trade statistics show that without oil revenue, Nigeria consistently had unfavourable balance of payment since the 1980s, and that more than 43% of total import into Nigeria is consumer goods (CBN 2011)[39]. If remittance coefficient is significantly positive in determining private domestic consumption and given that more than 43% of total import is on consumer goods, a large chunk of remittance funds may have been channelled on imported consumer goods rather than investment goods, especially if they are perceived to be permanent.

4.2.2 Investment Expenditure-Remittance model

The positive determinants of domestic investment in Nigeria include: GDP and its one quarter lagged value, and exchange rate; while remittance and interest rate are negative determinants (table 1b). Theoretically, higher GDP and its lagged value increase per capita income and hence savings and investment expenditure. Our empirical results is in tandem with this theoretical postulation, that is, a 1% increase each in GDP and its lagged value significantly promote investment expenditure by 20% and 22% respectively in a quarter, ceteris paribus. On its part, remittance coefficient is negative, though insignificant, thus providing sufficient evidence to support the theoretical thesis that remittance is at best used for other purposes than promote investment in productive or business activities (Durand, Parrado, and Massey, 1996)[21]. Specifically, a 1% increase in remittance receipt in a quarter depresses investment expenditure by 0.06% in the long run. Available data on investment indicate that despite tremendous increase in remittance inflow into Nigeria, investment rate and its GDP ratio have not exceeded 10% and 15% respectively since 1986 (figure 3).

Source: Researchers' regression results for macroeconomic model of Workers' remittances inflow to Nigeria using E-Views version 6

The coefficient of prime lending rate (interest rate) is also in tandem with the theoretical thesis that the cost of capital is important in making a decision whether or not to invest. A higher cost of capital will ultimately scare investors and reduce investment decisions. Available data on prime lending rate shows that average rate since 1986 is above 22%. Hence, our result show that a percent increase in interest rate significantly hurt investment expenditure in Nigeria by 0.01%, all things being equal.

4.2.3 National Income-Remittance model

The final estimated national income-remittance equation was specified as a function of consumption, investment, government expenditure, export and import proceeds, and remittance. The paper attempts to investigate the direct role of remittance on growth complimented by indirect contribution of other explanatory variables. Positive determinants of growth as reported in table 1c include: investment and export. Negative determinants include: private and public consumption expenditure, import, and remittances. Only investment, export and import coefficients met the a priori expectation.

The estimated results reveal that investment and export individually promote growth as relatively larger marginal propensities generated larger multiplier effect in the long run. The conclusion is premised given that a percent increase each in investment and export coefficients result in approximately 10% and 32% positive and significant change in growth proxied by GDP respectively, ceteris paribus. Specifically, when export rises, production activities also increase thus motivating more production, employment and income. However, the coefficients of both private and public consumption expenditure unexpectedly displayed negative sign against theoretical postulation. But the negative sign of these coefficients can be explained following Oyejide and Raheem (1993) in Bogunjoko, (1998)[40] that most public expenditures (investment) in Nigeria were doubtful in utility and viability and constituted a dead-weight loss in terms of net benefits to Nigeria's economy. The country's 136th position out of 175 countries ranked in 2014 in corruption index (perceived level of public sector corruption) further corroborated and reinforced Oyejide and Raheem assertion. Equally, being an import dependent-consumer nation, the import content of public and private consumption expenditure may have given rise to these negative coefficients. Thus, the failure of private and public consumption expenditure coefficients to conform to a priori sign is not surprising given the import-content of household and government consumption expenditures in Nigeria. As ratio of GDP, figure 3 displays the rising trends of private, public and import consumption expenditures.

Remittance coefficient is insignificantly negative in the long run, corroborating the earlier results obtained in a related work by Ogbonna, Agu and Chijioke (2014)[35]. Specifically, our findings reveal that as 1% remittance receipts enters the Nigerian economy, output growth depresses by 0.004%. That import coefficient is negative and significant is expected in an import-dependent economy like Nigeria. Thus, the theoretical explanation of the depressing impact of import on national economies is upheld in this study.

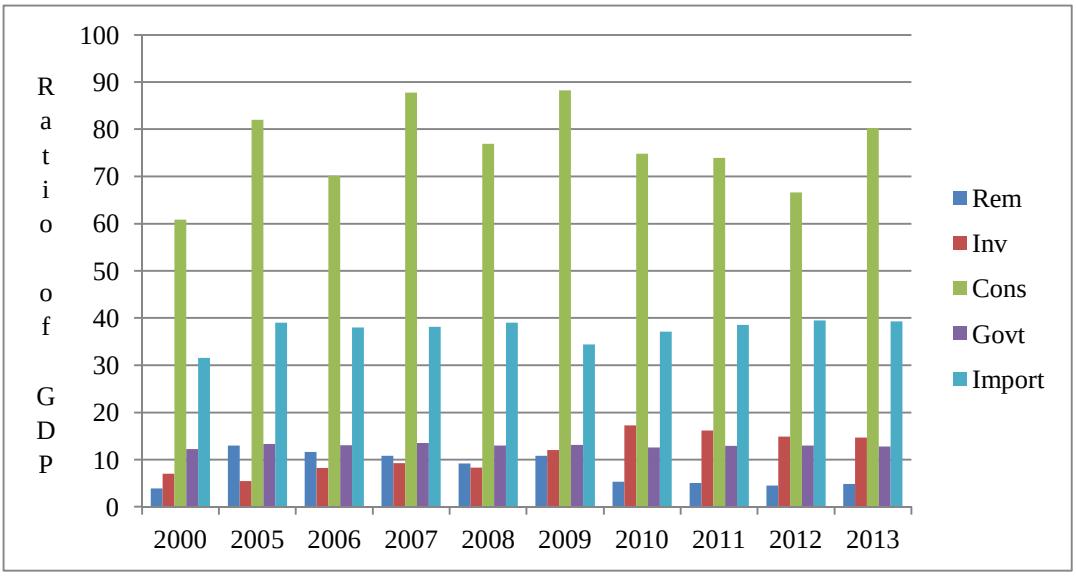

Figure 3: Remittance (Rem), Investment (Inv), Consumption (Cons), Government Expenditure (Govt), and Import (Imp) as ratio of GDP in the period 2000-2013

The error correction (ecm_{t-1}) coefficient in models 4, 5, and 6 (table 1a,b, and c) are -62, -42, -49 and highly significant, indicative of a long run convergence speed of 62%, 42% and 49% respectively. Hence, any disequilibrium in the long run relationship among consumption expenditure and its determinants, investment expenditure and its determinants, and national income and its explanatory variables, automatically adjusted back to long-run equilibrium at the above respective rates (speed) per quarter.

Different test statistics for the three models confirm the robustness of the estimates. For instance, using adjusted R^2, the first model explained about 47 per cent of the variations in private consumption, the second explained about 59 per cent of changes in domestic investment, and the third also explained about 59 per cent of variations in national income. Durbin-Watson (DW) autocorrelation coefficient at approximately 2.0 and 1.9 in the first and second models respectively indicate the absence of autocorrelation among the explanatory variables. However, DW coefficient at approximately 1.3 for the third model signifies the presence of autocorrelation. Also, relevant information criteria confirm there were no specification errors.

4. CONCLUSION

The question whether remittance is consumed or invested in Nigeria has been explored in this study. The use of OLS econometric technique in an ECM framework has proved quite intuitive and useful. The empirical results reveal astoundingly that remittance income is significantly consumed but not invested. Its deficit effect on the balance of payment derived from import content of consumption transmits depressing shock on domestic investment and economic growth in Nigeria. Hence, remittance, the much touted and acclaimed second largest source of external finance, though promotes daily consumption requirements, has growth-reducing impact on investment and growth in Nigeria. Thus, the brain drain syndrome, heightened by the ever increasing number of migrants, but assumed to have been mitigated by remittance inflow is disproved as remittance is significantly used to promote import content of foreign trade.

Our results also show that GDP, its one quarter lag, and exchange rate are positive determinants of consumption and investment, while deposit and prime lending rates are negative determinants respectively. The determinants of Nigeria's economic growth include investment and export, while private and public consumption, and import are depressing factors.
