

Effect of *Bacillus subtilis* TLO3 amylase pre-treatment on ethanol production from raw starches

Abstract

Bioethanol is currently the most widely used liquid biofuel in the world. Starch rich crops occupy the first place as biomass for bioethanol production. Amylases (EC 3.2.1.1) are enzymes that hydrolyse starch into sugar units, and pre-treating starch with amylolytic bacteria or directly by amylase might have a positive effect on fermentable sugars concentrations and ultimately result in increased ethanol yields.

In this study, an amylase producer strain *Bacillus subtilis* TLO3 newly isolated from rhizospheric soil was used for amylase production; after investigating the best combination of physico-chemical parameters. The crude enzyme was used for the pre-treatment of raw corn and wheat starches. Immediately afterwards, the yeast *Saccharomyces cerevisiae* was inoculated into the saccharified starch solutions for fermentation. Measures were done for total reducing sugars and ethanol production all along the fermentation process.

Thus, the best amylase production was obtained using 0.5% starch; 0.5% xylose; 0.25% urea; 2.5% NaCl; 3% bacterial inoculum; pH 7; temperature 50°C and 24h incubation time.

Amounts of reducing sugars of 70% and 91% were obtained after saccharification of wheat and corn starch, respectively, by crude amylase. The fermentation process monitoring showed a continuous decrease in the total sugars, concurrently with an increase in ethanol production that reached 0.92 g/l (2%) for wheat flour and 1.1 g/l (2.4%) for corn flour after 24 h.

Keywords: amylase; optimization; *Bacillus subtilis* TLO3; bioethanol; pre-treatment; raw starch; *Saccharomyces cerevisiae*.

26 **Introduction**

27 Throughout the 20th century, oil and its derivatives became the main energy source, thus
28 leading to a global economic dependence [1]. Besides this, fossil fuels are a
29 major contributor to greenhouse gases emissions, leading to global climate changes. Biomass
30 can make a substantial contribution to supplying future energy demand in a sustainable way.
31 It is presently the largest global contributor of renewable energy [2]. Bioethanol is currently
32 the most widely used liquid biofuel in the world. Global ethanol production was about 13000
33 million gallons in 2007, and production has almost doubled over the past years, with a
34 production approaching 26000 million gallons for 2015 [3]. Bioethanol can be produced
35 using different biomass, but at present it is produced exclusively via 1st generation
36 technologies, utilizing sugar and starch-rich feedstocks, as no commercial size 2nd generation
37 cellulosic ethanol facilities are presently in operation [4]. Starch is a natural, cheap, available,
38 renewable, and biodegradable carbohydrate polymer produced by many plants as a source of
39 stored energy. Bioethanol production using starch rich materials, represents a cost-effective
40 means for the production of bio-alcohol comparing to the use of lignocelluloses [5]. Corn is
41 the dominant material in the starch to ethanol transformation industry worldwide
42 [6]; however, wheat is the first available material for the production of bioethanol in some
43 regions [4]. Traditional conversion of starch into alcohol requires a two-stage process:
44 hydrolysis of starch by acid or amylolytic enzyme and fermentation by anaerobic bacterium or
45 yeast. Simultaneous saccharification and fermentation with mixed cultures is an effective
46 method for the direct fermentation of starch offering the advantages of realization in one
47 reactor and the glucose produced is rapidly converted into ethanol [7]. However, in this
48 system the ethanol yield decreases because starch is consumed by the growth of amylolytic
49 microorganisms. To increase the production of ethanol, it is necessary to breed a
50 microorganism by a genetic manipulation, which can directly ferment starch into

51 ethanol[8].In the present study, two starch-rich products (wheat and corn flours); were used
52 as substrates for the production of ethanol. The raw starch contained in the flours was pre-
53 treated with crude amylase produced by the strain *B. subtilis* TLO3, which optimal
54 production conditions were previously investigated. Thereafter, the released sugars in
55 solution were fermented using the yeast *S. cerevisiae*. The results obtained for the two flours
56 were compared to determine the effect of amylase pre-treatment on each substrate concerning
57 starch hydrolysis and thus ethanol production.

58 **Methodology**

59 **1. Biological material**

60 Wheat (*Triticum durum*) and corn (*Zea mays*) flours were used as starch-rich substrates for
61 the production of bioethanol.The strain *Bacillus subtilis* TLO3 (accession number
62 KR262718) was isolated aseptically(15 cm depth) from rhizospheric soil of olive tree in the
63 region of Tlemcen (Algeria)and selected after a screening program from different sources
64 based on amylase production and physiological features (data not shown). The strain *S.*
65 *cerevisiae*S288Cwas obtained from a commercial source.

66 **2. Amylase production optimization**

67 Medium composition and production conditions were optimized to obtain the best
68 combination for optimal amylase production by the strain *B. subtilis* TLO3. The optimization
69 was done using the One-Variable-at-Time(OVAT) method and amylase activity was analysed
70 by estimating the released reducing ends of sugar according to the dinitrosalicylic acid (DNS)
71 method of Miller[9]. The sample to be assayed was mixed with starch 1% (v/v)buffered in
72 sodium phosphate pH 6.8; then the mixture was incubated for 30 min at 50°C. The reaction
73 was stopped by adding the same volume of DNS reagent and boiled for 10 min at 100°C. The
74 absorbance was read using a spectrophotometer at 540nm.

75 The experiments were realized using basal media containing 5g potato starch and 2g yeast
76 extract per 1000 ml distilled water (w/v), with pH 7 and shaking at 150 rpm. The production
77 media were sterilized by autoclaving at 121°C for 20min. The flasks were then cooled and
78 inoculated with the 4% (v/v) *B. subtilis* TLO3 culture seed ($DO_{600} = 0.05$).

79 The following parameters were tested: secondary carbon sources (glucose, cellobiose, sucrose,
80 xylose, galactose, lactose, cellulose, tween 20, tween 80, glycerol (0,5%) (w/v); nitrogen
81 sources (peptone, casein, yeast extract, urea, gelatine (0,25%) (w/v), sodium nitrate and
82 sodium nitrite (0,5%) (w/v); NaCl concentration (2,5 , 5, 10, 15, 20, 25% (w/v)) ; pH
83 (5,6,7,8,9,10); Temperature (28°C, 37°C, 50°C, 60°C and 80°C); Inoculum size (0,5, 1, 2, 3, 4,
84 5% (v/v)) and incubation time (24, 48, 72 hours).

85 3. Amylase production

86 Two 500 ml flasks containing 120 ml amylase production optimized medium were prepared.
87 The strain *B. subtilis* TLO3 was cultivated on nutrient broth for 24h at 50°C. Three per cent of
88 the culture (v/v) was inoculated to the amylase production media. After 24h of incubation at
89 50°C under orbital shaking 150 rpm, the media were centrifuged at 10000 rpm during 10 min
90 at 4°C and the supernatants were used as crude amylase for the saccharification of the flours.

91 4. Wheat and corn flours saccharification

92 Ten grams of each flour was added to the crude supernatant then incubated under orbital
93 shaking 150rpm at 45°C for 4h for wheat flour, and at 35°C for 24h for corn flour, in
94 accordance with time and temperature of saccharification necessary for each starch [10, 11].
95 Samples were taken every hour and centrifuged at 10000 rpm for 10min to determine the
96 amount of reducing sugars released. Media were finally centrifuged at 10000 rpm for 10 min
97 at 4°C; then the supernatants autoclaved at 121°C for 20 min.

98 5. Reducing sugars fermentation using *Saccharomyces cerevisiae*

99 The strain *S. cerevisiae* S288C was cultivated on a Peptone-yeast-glucose PYG medium
100 containing 1.25g peptone; 1.25g yeast extract and 3g glucose per 1000ml of distilled water
101 (w/v); for 48h at 30°C. Each saccharification medium was inoculated with 5% yeast
102 culture (v/v) ($DO_{600} = 0.05$). The media were then incubated at 30°C for 24h and samples were
103 taken each hour for the monitoring of reducing sugar and ethanol concentrations.

104 **6. Determination of reducing sugars and ethanol production**

105 The amount of reducing sugars was measured before and after flours saccharification and
106 throughout the fermentation process using the DNS method [9]. Concerning the ethanol
107 production, it was determined by the colorimetric method described by Sumbhate *et al.* [12]. A
108 mixture containing 0.5ml sample to be assayed, was mixed with 0.5ml sodium dichromate
109 reagent; 0.5ml acetate buffer pH 4.3 and 2.5ml sulphuric acid 1N. The solution was then
110 vortexed for 1min then incubated at room temperature for 120min. The absorbance was read
111 at 578nm using a spectrophotometer and a standard curve was plotted using different ethanol
112 concentrations.

113 **Results and discussion**

114 **1. Amylase production optimization**

115 The highest amylase production (367 ± 6 U/ml) was obtained using 0.5% starch as essential
116 carbon source, 0.5% (w/v) xylose as secondary carbon source, 0.25% (w/v) urea as nitrogen
117 source, 2.5% (w/v) NaCl and 3% (v/v) inoculum size. The production was at its optimum at
118 initial pH 7, temperature 50°C and 24 h incubation period at 150 rpm shaking.
119 Many Firmicutes bacteria are able to utilize xylose as carbon source (Gu *et al.*, 2010). Xylose
120 may be implied in ribose synthesis, an important sugar in nucleic acid formation. Indeed,
121 Parket *et al.* [13] reported the isolation of transketolase deficient *B. subtilis* strain, which was
122 able to produce D-ribose from xylose. Nahas and Waldemarin [14] showed that xylose was

123 among the best supplementary carbon sources for highest amylase production using the fungi
124 *Aspergillusochraceus*.

125 Among organic and inorganic nitrogen sources employed, urea showed the highest amylase
126 activity, followed by sodium nitrate. This shows that this strain has no preference between
127 inorganic and organic nitrogen source for amylase production. Nagarajan *et al.*, [15]reported
128 maximum amylase production by *B.subtilis* strain using urea as nitrogen source.

129 The high production yield noted at high temperature is an asset in industrial enzyme
130 production because it influences both bacterial growth and amylase production[16].Many
131 studies reported optimum amylase production in this temperature range using *Bacillus* strains
132 [17, 18, 19].

133 Also, maximum amylase production in short time(24h), represent promising results for
134 application at large scale allowing considerable energy savings.Similar works reported
135 maximum amylase activity after 24h using *Bacillus* strains [20, 21].Optimization results are
136 presented in Table 1.

137 **2. Wheat and corn flours amylase pre-treatment**

138 Flours starch saccharification was performed using crude amylase produced by *B. subtilis*
139 TLO3 (Figure 1, Figure 2).A good yield of released reducing sugars was noted for both
140 flours. Thus, percentages of 70% and 91% of reducing sugars were obtained during the
141 saccharification of wheat and corn flours, respectively; proving the efficiency of starch
142 saccharification of the crude amylase produced by *B. subtilis* TLO3. Several studies reported
143 raw starch saccharification for bioethanol production using amylase produced by *Bacillus*
144 *spp.* strains[22, 23, 24, 25].

145 **3. Fermentation of reducing sugars and ethanol production**

146 The monitoring during 24h of reducing sugars fermented and ethanol produced is shown in
147 Figure 3 and Figure 4. The choice of an incubation time of 24h for the fermentation was

148 motivated by the advantage of production of ethanol in a short time which allows doing
149 considerable energy savings. The reducing sugars concentration at the beginning of the
150 fermentation was 100 µg/ml and 165 µg/ml, for wheat and corn flours, respectively. This
151 difference could be due to the starch content of corn 79% [26], which is superior to that of
152 wheat 62% [27]. The presence of resistant starch inaccessible to amylase enzymes up to 13%
153 for wheat flour and 8.1% for corn flour [28], can also explain that difference. The monitoring
154 of reducing sugars concentration during the fermentation showed a slight increase in the 3
155 first hours, which can be explained by a secretion of amylase by the yeast. Indeed, the strain *S.*
156 *cerevisiae* S288c possesses an α -glucosidase MAL32 expressed in early log phase [29]. This
157 was followed by a continuous decrease reaching 42% and 79% less for wheat flour and maize,
158 respectively, comparing to initial concentrations. This decrease indicates clearly that the yeast
159 transformed the reducing sugars obtained after the saccharification of the flours
160 starch. Concerning ethanol production, the monitoring showed a production yield of 0.92 g/l
161 (2%) for the wheat flour and 1.1 g/l (2.4%) for the corn flour after 24h. For the wheat flour
162 the production was steady during the 4 first hours, and then a continuous increase was noticed
163 from the fifth hour. For the corn flour, after an increase during the 3 first hours, the amount of
164 ethanol declined during 3 hours, then resumed the increase in a continuous manner until 24h.
165 This decrease could be due to a contamination by an acetic acid bacteria, which could
166 ferment ethanol and transform it to acetic acid by an oxydo-reduction reaction [30, 31, 32],
167 which represents a limiting factor in bioethanol production process. The best ethanol yield
168 was obtained using corn flour because of the higher starch content, and thus fermentable
169 sugars. Evaluative studies concerning starch for ethanol yield optimization described five
170 criteria that influence the functional properties of starch: amylose/ amylopectin content [33,
171 34, 35, 36, 37], the morphology of starch granule [38], the fine structure of amylopectin [39,
172 40, 41], thermal properties [34, 36] and pasting properties [36].

173 **Conclusion:**

174 Bioethanol production using starch rich substrates remains, to the present, the most cost-
175 effective means for bio-alcohol production; due to ease of saccharification comparing to
176 lignocelluloses. Amylase production optimization has indicated that *B.subtilis* TLO3 is a
177 promising candidate for starch transformation industry due to high amylase activity,
178 production at high temperature and reduced time. Raw corn and wheat starches were pre-
179 treated with crude amylase produced using the obtained parameters combination and high
180 saccharification yields were obtained. Also good ethanol production was achieved, after
181 fermentation of the released reducing sugars by the yeast *S. cerevisiae* S288C.
182 Corn flour showed the best saccharification yield and ethanol production, confirming that it
183 is, so far, the best starch substrate for ethanol production. For further improvement, statistical
184 design optimization of bioethanol production conditions is envisaged, with the aim to achieve
185 a successful scale-up to industrial level production.
