3

Aims: Biomimetic surface modifications have gained significant attention in fabric innovations. In this study, elephants mud bathing was mimicked to create a superior hydrophilic nylon fabric. Place and Duration of Study: Sri Lanka institute of nanotechnology and University of Moratuwa, Sri Lanka, between June 2017 and March 2018.

Methodology: Bentonite nanoclay was grafted on nylon using silane as a coupling agent. Fourier transform infrared spectrophotometry, Scanning electron microscopy, Energy dispersive X-ray spectroscopy and thermogravimetric analysis confirmed the successful grafting of nanoclay on nylon wettability while the was proved using textiles protocols. Results: Infrared spectroscopy and elemental analysis confirmed the presence of organic chains and Si groups in bentonite nanoclay modified nylon fabrics. The accomplishment of the surface modification was quantitatively proved by thermogravimetric analysis. SEM images clearly show a thin layer of clay on nylon fibres after being treated with bentonite nanoclay. BNC coated nylon show superior wettability and dryability results. **Conclusion:** It is expected that this bio-inspired wettable nylon fabric may break the barrier of using nylon in various hydrophilic textile applications.

1. INTRODUCTION 14

15

16 Moisture management is one of the key performance criteria in today's apparel industry [1]. However, high demanded synthetic fabrics such as nylon are lack in moisture management property due to their 17 hydrophobic nature. Nylon fabrics are excellent in mechanical, thermal, and chemical properties. Yet, 18 19 Nylon fabric is weak in particular properties such as anti-electrostatic property, lack of comfortable 20 touch with human skin, and low moisture regain [2]. Hence, new chemistries for surface modifications 21 in creating hydrophilic nylon fabrics to meet market needs have received much attention [3, 4]. Nature 22 always provides sustainable, cost-effective, and flexible alternatives for various problems of the eco 23 system [5, 6]. By mimicking the nature's way of cooling elephant's body temperature using mud, 24 nanoclay was identified as an ideal sustainable solution to develop a wettable nylon fabric. The nano 25 size space between adjacent platelets of bentonite nanoclay (BNC) comprises of exchangeable 26 cations, which draw water and form a rigid network made up of water layers [7, 8]. Hence, this 27 nanospace is vital for BNC's incomparable hydrophilicity. In this study, a silane coupling agent couples BNC and nylon with the intention of increasing hydrophilic properties of nylon. 28 29

30 2. METHODOLOGY

31

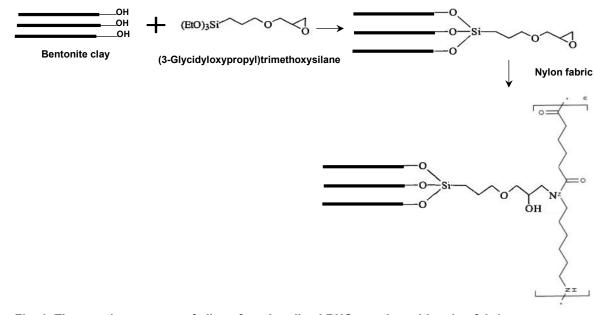

32 Purified nylon was stirred in 2 mmoldm-3 of (3-Glycidyloxypropyl)trimethoxysilane solution for 1 hour. 33 APTES modified fabric was padded and cured at 110 °C and washed thoroughly. Then, the fabric was 34 dipped in a dispersion of BNC for 1 hour. Dipped fabric was padded and cured at 110 °C and washed 35 thoroughly. BNC grafted and pristine nylon fabric samples were characterized by Fourier transform infrared spectrophotometry (FTIR), Scanning electron microscopy (SEM) and Energy dispersive X-ray 36 spectroscopy (EDX). Thermogravimetric analysis (TGA) was carried out on an SDT Q600 37 38 thermoanalyser (TA Instrument, sample mass ~10 mg; heating rate 10 °C/min; nitrogen flow). 39 Wettability of fabric samples was measured using ASTM TS-018 protocol. A drop of distilled water 40 was allowed to fall onto fabric sample, and the time taken for water to get fully absorbed into the fabric was recorded. The absorptive capacity of fabrics was tested using ASTM D1117-80 protocol. Five 41 samples (76 mm²) of treated and pristine nylon were weighed and dipped in distilled water for 5 min 42 43 and hung vertically for another 5 min to allow extra water to drip down. Finally, fabrics were weighed 44 again. The drying rate of fabric was measured by exposing to 10 µL of water, while in contact with a 45 heated plate set to 37 °C (human body perspiring temperature). To check the stability of BNC coating 46 on nylon, 20 washing cycles were performed at 50 °C with non-ionic detergent Ultravon CN Ciba for 47 45 min (AATCC 61 (2A)).

48

49 3. RESULTS AND DISCUSSION

50 51 (3-Glycidyloxypropyl)trimethoxysilane was employed as a coupling agent and the methoxy groups first 52 hydrolysed into hydroxyl, and then reacted with the silanol on the BNC. Epoxy group reacted with 53 amide. The reaction process is shown in Fig. 1. The presence of characteristic absorption bands in 54 FTIR spectra of BNC grafted nylon proves a new bond formation between silane modified BNC and nylon fabric. Absorption bands in 1200-1000 cm⁻¹ in spectrum B (Fig. 2.) show the strong broad band 55 which is attributed to valence vibration of Si-O. This confirms that silane coupling agent has bound 56 57 with nylon fabric. Green colour region in spectrum D (Fig. 2.) shows a broad intense absorption band 58 (above 3420 cm⁻¹) due to vibrations of OH⁻ groups in water molecules of clay, participating in the 59 formation of hydrogen bonds. In spectrum D (Fig. 2.), intensive bands in approximately 1200-1100 60 cm⁻¹ represent the asymmetric stretching of siloxane groups (Si–O–Si). Hence, FTIR spectra show 61 that nylon has been modified by clay successfully.

65

 nylon and (D) washed BNC functionalized nylon.

69

SEM image of pristine nylon fabric (Fig. 3. A) indicates a smooth fibre surface after the purification. SEM images in Fig. 3. B and C clearly show a thin layer of BNC on nylon fibres after being treated with BNC. After the tenth washing cycle, the surface morphology (Fig. 3. D) is same as the unwashed sample. BNC grafted nylon was further proved by EDX analysis (Fig. 4.) showing presence of significant amounts of silicon, aluminum, calcium, sodium, and magnesium elements.

grafted nylon.

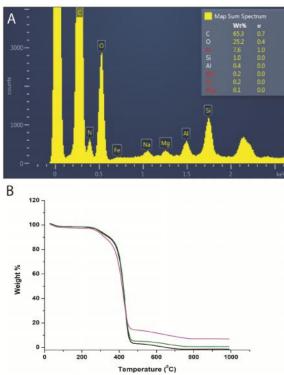

Fig. 4. (A) SEM-EDX spectrum of BNC functionalized nylon and (B) Thermograms for pristine
 nylon (Black), silane functionalized nylon (Green) and BNC grafted nylon (Purple).

The resulted thermograms show that pristine nylon fabric (Fig. 4. (B) Black) undergoes thermal degradation beginning at 452 °C and with a total mass loss of 98%. However, silane modified nylon (Fig. 4. (B) Green) undergoes the same degradation, with a lesser mass loss of 97% compared to pristine nylon. It is due to the organic and inorganic Si contents in (3-Glycidyloxypropyl)trimethoxysilane. BNC modified nylon fabric (Fig. 4. (B) Purple) undergoes the same degradation with even a lesser mass loss of 94% compared to silane modified nylon fabric. The 6% residue remain is due to BNC bound to nylon fabric.

93 *(B-A)/A 94 **0.010/drying time

95

96 Excellent wettability, water absorptive capacity and drying rate of BNC grafted nylon (Table 1.) 97 confirm the superior wettability of the nano modification due to instant diffusion of water into nanospace and clinging of water with hydroxyl groups on the surface of BNC. The surface 98 99 morphology and the wettability of 20 times washed BNC grafted nylon remained same as before wash 100 samples confirming the covalent bond between the fabric and the coating. In fact, the siloxane bond between (3-Glycidyloxypropyl)trimethoxysilane and BNC, and the amide bond between BNC and 101 102 polyester fabric, have given the best adhesion and washing resistance properties to the treated nylon 103 fabric [9].

104

105 4. CONCLUSION

106

BNC coating on nylon appears as a convenient green modification route to produce a wettable nylon
 which can be used for many hydrophilic fabric applications apart from its excellent ability to substitute
 expensive natural fibre usage in clothing.
