2 # The role of monocarboxylate transporters and their chaperone CD147 in
3 lactate efflux inhibition and the anticancer effects of *Terminalia chebula* in
4 neuroblastoma cell line N2-A

5

6 **ABSTRACT**

7 **Aims:** In the presence of oxygen, most of the synthesized pyruvate during glycolysis in the cancer cell
8 of solid tumors is released away from the mitochondria to form lactate (Warburg Effect). To maintain
9 cell homeostasis, lactate is pumped across the cell membrane by monocarboxylate transporters
10 (MCTs). The major aim of the current investigation is to identify novel compounds that inhibit lactate
11 efflux that may lead to identifying effective targets for cancer treatment.

12 **Study Design**: In this study, 900 ethanol plant extracts were screened for their lactate efflux inhibition
13 using neuroblastoma (N2-A) cancer cell line. Additionally, we investigated the mechanism of inhibition
14 for the most potent plant extract regarding monocarboxylate transporters expression, and
15 consequences effects on viability, growth, and apoptosis.

16 **Methodology:** The potency of lactate efflux inhibition in ethanol plant extracts were evaluated in N2-A
17 cells by measuring extracellular lactate levels. Caspase 3- activity and acridine orange/ethidium
18 bromide staining were performed to assess the apoptotic effect. Antiproliferative effect was measured
19 by using WST assay. Western blotting was performed to quantify protein expression of MCTs and their
20 chaperone CD147 in treated cells lysates.

21 **Results:** *Terminalia chebula* plant extract was the most potent lactate efflux inhibitor in N2-A cells
22 among the 900 tested plant ethanol extracts. The results obtained show that ethanol extract of
23 *Terminalia chebula* fruits (**TCE**) significantly ($P = 0.05$) reduced the expression of the MCT1, MCT3,
24 MCT4 and the chaperone CD147. The plant extract was more potent (IC_{50} of 3.59 ± 0.26 µg/ml) than
25 the MCT standard inhibitor phloretin (IC_{50} 76.54 ± 3.19 µg/ml). The extract also showed more potency
26 and selective cytotoxicity in cancer cells than DI-TNC1 primary cell line (IC_{50} 7.37 ± 0.28 vs. 17.35 ±
27 0.19 µg/ml). Moreover, **TCE** Inhibited N2-A cell growth (IG_{50} = 5.20 ± 0.30 µg/ml) and induced
28 apoptosis at the 7.5 µg/ml concentration.

29 **Conclusion**: Out of the 900 ethanol plant extracts screened, *Terminalia chebula* ethanol extract was
30 found to be the most potent lactate efflux inhibitor with the ability to inhibit chaperone CD147
31 expression and impact the function of monocarboxylate transporters. Furthermore, TCE has growth
32 inhibition and apoptotic effects. The obtained results indicate that the plant *Terminalia chebula*

constituent(s) may contain promising compounds that can be useful in the management of neuroblastoma cancer.

Keywords: plant ethanol extracts; monocarboxylate transporters; CD 147; lactate inhibitor; apoptosis; growth inhibition.

1. INTRODUCTION

Unlike normal cells, solid tumor relies on aerobic glycolysis as the primary source of energy, a phenomenon known as the Warburg Effect [1]. As the end-product of glycolysis, lactate is produced in an excessive amount [2] and considered an alternative source of fuel for the uncontrolled cell proliferation [3]. Lactate efflux to the cell microenvironment is critical to cell survival. The extracellular acidosis will enhance cancer cell invasiveness [4], metastasis [5], and chemotherapy resistance [6]. On the other hand, ~~since~~ the continuous lactate production will cause intracellular acidosis. The acidic intracellular pH will eventually initiate apoptosis, [7, 8] through different mechanisms such as promoting the permeability of mitochondria membrane [9], activating endonucleases that cause DNA fragmentation [10], or activating caspase-3 protease, the key indicator of apoptosis that deactivates essential metabolic proteins [11]. ~~On the other hand, extracellular acidosis will enhance cancer cell invasiveness [4], metastasis [5], and chemotherapy resistance [6].~~

The mammalian cell has many transporters involved in the regulation of pH homeostasis [12]. However, monocarboxylate transporters (MCTs) are considered the most important pH cell regulators, especially within tumor cells with rapid metabolism and high glycolysis rate [13]. These MCTs (also known as solute carrier 16, SLC16 proteins) are a family of 14 transporters, and the first four members (MCT1-MCT4) documented as single-carboxylate molecules transporters across the biological membranes [14]. MCT1 is considered high-affinity lactate transporter involved in exogenous lactate uptake by the cancer cells [15], that facilitate lactate efflux according to pH gradient [16]. On the other hand, the low-affinity lactate transporters MCT4 release lactate, the end product of glycolysis [2]. Moreover, it was recently reported that MCT3 is involved in lactate efflux of some cells [17].

Natural products have played a very important role as established cancer chemotherapeutic agents [18]. Moreover, flavonoids were found as MCTs inhibitors [19]. MCTs are attractive targets for cancer therapy, especially in cancers of a hyper-glycolytic and acid-resistant phenotype [20]. Therefore, this study was designed to identify potent natural lactate efflux inhibitors among 900 plant extracts and to explore their mode of inhibition. Furthermore, the consequential effects of these extracts on cell viability, proliferation, and apoptosis were also addressed.

65 **2. METHODOLOGY**

66 Screened plants and herbs were obtained from several sources including Frontier Natural
67 Products Co-op (Norway, IA, USA), Monterey Bay Spice Company (Watsonville, CA, USA), Mountain
68 Rose, Herbs (Eugene, OR, USA), Mayway Traditional Chinese Herbs (Oakland, CA, USA), Kalyx
69 Natural Marketplace (Camden, NY, USA), Futureceuticals (Momence, IL, USA), Organic Fruit
70 Vegetable Markets and Florida Food Products Inc. (Eustis, FL, USA). L-lactate assay kits were
71 obtained from Eton Bioscience (Saint Diego, CA, USA), and water-soluble tetrazolium (WST)
72 proliferation assay kits from G-Biosciences (St. Louis, MO, USA). EnzChek® Caspase-3 Assay were
73 purchased from Life Technologies Inc., (Grand Island, NY, USA). Resazurin (7-hydroxy-10-oxido-
74 phenoxazin-10-ium-3-one), a-cyano-4-hydroxycinammic acid (CHC), phloretin and absolute ethanol
75 were obtained from Sigma-Aldrich Co. (St. Louis, MO, USA). Other laboratory supplies were obtained
76 from VWR International (Radnor, PA, USA), Atlanta Biological (Flowery Branch, GA, USA), and Santa
77 Cruz Biotechnology, Inc. (Dallas, TX, U.S.A).

78 Primary antibodies monocarboxylate transporter 1(MCT1), monocarboxylate transporter 3
79 (MCT3), monocarboxylate transporter 4 (MCT4), Basigin (CD147), and glyceraldehyde 3-phosphate
80 dehydrogenase (GAPDH), secondary antibody and chemiluminescence reagent, were provided by
81 Abcam (Cambridge, MA, USA). Pierce protein assay kit was purchased from Thermo Scientific
82 (Rockford, IL, USA). Bio- Rad (Hercules, CA, USA) supplied running and transferring buffers, standard
83 protein ladder, Laemmli sample buffer, and nitrocellulose. RIPA lysis buffer and mammalian protease
84 arrest were obtained from G-Biosciences (St. Louis, MO, USA).

85 **2.1. Plant Extraction**

86 The screened plants were extracted with ethanol, the most common and safe organic solvents
87 in pharmacological studies evaluating the activity of medicinal herbs [21]. Briefly, the selected plants
88 were grounded, homogenized in 99.5% ethanol, and then placed in the dark on a shaker for 24 h at RT.
89 Plant-ethanol mixture stored in air tight 15 ml glass containers at -20℃ in the dark until the time o f the
90 study. Further, the identified plant extract for more investigation, *Terminalia chebula* fruits (**TCE**) was
91 finely grounded and extensively extracted by soaking in 99.5% ethanol for seven consecutive days on a
92 shaker in dark and at RT. The plant-ethanol mixtures were filtered and dried under vacuum, using a
93 rotary evaporator below 40℃. The obtained crude e thanol extract of **TCE** was stored in the dark at -
94 20℃ for further studies.

95 **2.2. Cell Culture**

Mouse brain neuroblastoma cells (N2-A) and rat primary astrocytes (DI-TNC1) were purchased from American Type Culture Collection (ATCC, Manassas, VA). Cell culture Dulbecco's Modified Eagle Medium (DMEM), fetal bovine serum (FBS), penicillin/streptomycin, DPBS, and trypsin were all from Atlanta Biologicals (Atlanta, GA, USA). Cells were cultured in 75-cm TC flask at 37ºC in humidified 5% CO_2 incubator and were subcultured as needed with trypsin/EDTA. Growing media was supplemented with 10% FBS (v/v), 4 mM L-glutamine, and 1% penicillin /streptomycin.

2.3. ~~Plant extracts~~ ~~Extracts~~ High Throughput Screening for Lactate Efflux Inhibition

For screening plant extracts as lactate efflux inhibitors, N2-A cells (5×10^4 /well) were seeded in 96-well plates and treated with 50 - 1000 µg/ml of plant ethanol extracts in a final volume 200 µl/well experimental media (phenol-free media supplemented with 1% each FBS/penicillin/streptomycin). Control wells were treated only with ethanol at the highest used concentration (≤1.0%). After 4 h exposure period at 37ºC and 5% CO_2, 50 µl each of both experimental media and the lactate kit substrate mix were combined in another 96-well plate. The reaction was extended for 30 min at 37ºC, CO_2 -free incubator and stopped by 50 µl of 0.5 M acetic acid/well. The absorbance was measured at 490 nm using µQuant Monochromatic Microplate Spectrophotometer (BioTek, USA).

2.4. TCE Studies

2.4.1 Lactate Efflux Assay

As lactate efflux inhibitor, the effect of **TCE** was compared to standard MCT inhibitors, phloretin, and α-cyano-4-hydroxycinammic acid (CHC). N2-A cells were exposed to gradual concentrations between 0 to 250 µg/ml. All experiments were performed at least two separate times with n=4, and the control cells were exposed to the used solvents at the highest tested concentration (≤1.0% of ethanol for plant ~~extract or~~extract or 0.1 % DMSO for standard inhibitors). Blank wells without cells were also included in the test.

2.4.2 Cell Viability Assay

The redox dye resazurin was used for determining N2-A and DI-TNC1 cells viability after 24 h treatment with **TCE** at concentration range 0 – 250 µg/ml in experimental media. Control wells were treated only with ethanol at the highest used concentration (≤1.0%) and blank wells without cells were also involved in the test. In this assay, resazurin solution of 0.5 µg/ml in sterile phenol red free-phosphate-buffered saline (PBS) was used at concentration level 15% v/v. After an experimental

period, the reduced resazurin was measured at 570 nm using µQuant Monochromatic Microplate Spectrophotometer (BioTek, USA). The percentage of N2-A cell survival compared to the control was calculated for IC_{50}s determination.

2.4.3 Western Blotting

Neuroblastoma cells were plated in 6 wells plate at concentration 10^6 cells/well and treated with declining concentrations of **TCE** (5-0 µg/ml) in the experimental media. Control wells were treated only with ethanol at the highest used concentration (0.1%) and blank wells without cells were also included in the test. After 4 h of incubation, cells were washed with PBS, pelleted and lysed for 30 minutes on ice with RIPA lysis buffer contains 1 X mammalian protease arrest. Samples were pulsed for few seconds with a probe sonicator and centrifuged at 10,000 ×g for 10 minutes at 4°C and the protein concentrations in cell lysates were determined using protein assay BCA. After that, the supernatant was diluted (1:1) with Laemmli sample buffer and boiled at 100°C for 3 minutes. Proteins from total cell lysates were loaded at consistent concentration 40 µg/ml and separated at 200 v constant voltages for 30-40 minutes using 10% SDS-PAGE gels and running buffer. Proteins were transferred to nitrocellulose membranes in the ice-cold transferring buffer for 90 minutes at 100 Voltage. Nitrocellulose membranes were incubated on a rocking shaker at room temperature for 1 hour with blocking buffer (5% non-fat dry milk in 1X PBST, pH 7.6) followed by 3x wash. All membranes were then incubated overnight with 10 ml of primary antibodies – diluted blocking buffer as following: MCT1 (1µg/ml); MCT3 (2.5 µg/ml), MCT4 (1:800); CD147 (1: 2,000) and GAPDH (1 µl/ml). After 3X wash with PBST, membranes were reincubated at RT for 3 hours with secondary antibody at dilution (1: 5,000). Finally, nitrocellulose membranes were washed with PBST and developed with chemiluminescence reagent. Images were captured using a Flour-S Max ~~Multiimager~~Multiimager (Bio-Rad Laboratories, Hercules, CA) and analyzed to obtain the band density with Quantity One Software (Bio-Rad Laboratories, Hercules, CA).

2.4.4 Caspase 3 ~~apoptosis~~ Apoptosis Study

Apoptosis study was conducted by assessing caspase -3- activity using EnzChek® Caspase-3 assay kit. Briefly, N2-A cells were seeded at an initial concentration of 0.5 × 10^6 cell / well in 6 - well plates and treated with serial concentrations of **TCE** (0 - 30 µg/ml) in experimental media in a final volume of 3 ml/well. Control wells were treated only with ethanol at the highest used concentration (0.15 %) and blank wells without cells were also applied in the test. After 4 h incubation period, treated cells from each well were harvested, pelleted, washed in PBS. Cell pellets were resuspended in 50µL lysis buffer for 30 min on ice followed by centrifuge for 5 minutes at 4,100 ×g to pellet the debris. Lastly,

158 50 µl of each samples supernatant and the apoptosis kit substrate working solution were combined in
159 another microplate well for 30 min at RT and the background fluorescence was determined by using 50
160 µL of the cell lysis buffer. Fluorescence intensity for each sample was measured (excitation/emission
161 ~342/441 nm) using Synergy HTX Multi-Reader (BioTek, USA).

162

163

164 **2.4.5 Acridine Orange / Ethidium Bromide Apoptosis Study**

165 Acridine orange/ ethidium bromide staining assay was performed to detect apoptotic changes in
166 N2-A cells. The applied conditions for the assay were similar to the caspase-3 apoptosis study.
167 Monolayer treated cells were washed 3X with PBS and incubated with the stain for 30 min. The dyes
168 were added to the cells in 1:1 ratio at a final concentration of 5mg/mL acridine orange and 3 mg/ml of
169 ethidium bromide. The excess dye was removed, and cells washed 2X with PBS and imaged at 40X
170 magnification using Nikon Eclipse Ti fluorescence microscope (Nikon Instruments Inc., Melville, NY,
171 USAU.S.A).

172

173 **2.4.6 Growth Study and Morphological Changes**

174

175 Cyto Scan™ water-soluble tetrazolium (WST-1) assay was used to measure growth rate in N2-
176 A cells. Briefly, cells were plated at an initial density of 2 x10^4 cells / well in 96 well plate and treated
177 with **TCE** at concentration range (0 - 60 µg / ml) in a final volume 200 µl / well phenol-free growing
178 media. Control cells were exposed to 0.3% ethanol in culture media and corresponding blanks were
179 performed as treatments without cells. After 48 h of incubation, cells were combined with WST-1/CEC
180 assay reagent at 10% v/v for 30 min to 4 h and the generated dark yellow-colored formazan was
181 measured at 440 nm using Synergy HTX Multi-Reader (BioTek, USA). Cell density and morphological
182 changes were photographed under phase - contrast inverted microscope Olympus 1 X 7I (Pittsburgh,
183 PA, USA) at 20X magnification.

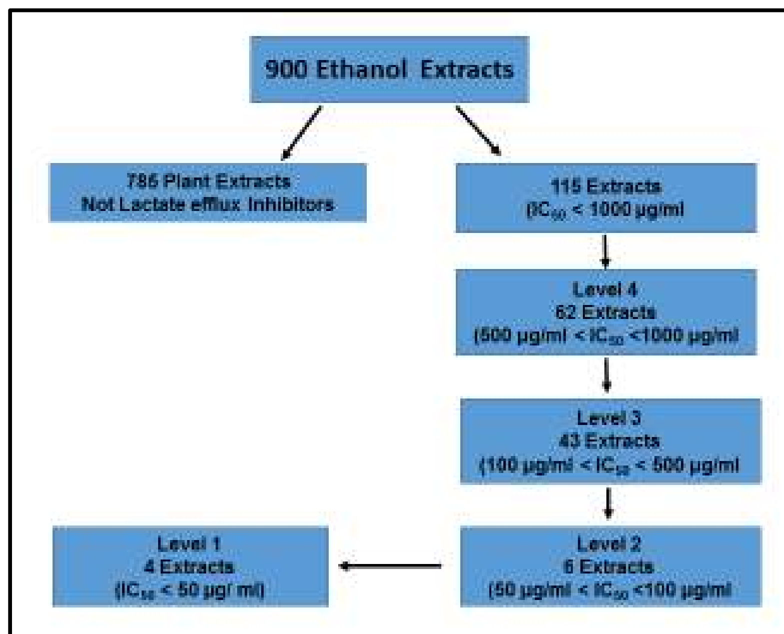
184 **2.5 Statistical Analysis**

185 Data were analyzed using the Graph Pad Prism 6.2 Software (San Diego, CA, USA). All data
186 points were obtained from the average of at least two independent studies and expressed as mean ±
187 SEM. Inhibitory concentrations (IC_{50}s) for lactate efflux and cell viability studies and IG_{50} for growth
188 inhibition studies, were determined by nonlinear regression with lowest 95% confidence interval and R^2
189 best fit. The significance of the difference between two groups was determined by unpaired t-test,
190 between control and treated groups using one-way ANOVA followed by Dunnett's multiple
191 comparison's test. Significance of the difference between the control and treated groups is considered
192 at *$P = 0.05$, ** $P = 0.01$, *** $P = 0.001$, and **** $P = 0.0001$.

193 **3. RESULTS**

194 **3.1. High Throughput Plant Extracts Screening for Lactate Efflux Inhibitors**

195 The high throughput screening of 900 ethanol plant extracts was designed to identify natural
196 potent lactate efflux inhibitors in N2-A cancer cells at four tiers (Plant extract concentration: 50 - 1000
197 µg/ml). Based on < 50% lactate efflux compare to the control, 785 (87%) of the tested plant extracts
198 were not active and excluded from the study after the first tier. The other extracts (115) were active and
199 categorized according to their potency into four levels (Figure 1 and Table 1). The fourth level were
200 considered the least potent and included 62 extracts with IC_{50} >500 < 1000 µg/ ml. 43 extracts showed
201 average potency (IC50 >100 < 500 µg/ ml) and placed on the third level and 6 extracts showed higher
202 potency (IC_{50} >50 < 100) at the second tier. Four plant extracts were categorized as the most potent at
203 level 1(IC_{50} < 50 /µg/ ml). These plant extracts were identified according to their potency as *Terminalia*
204 *chebula* (IC_{50} 42.78 µg/ ml), *Bupleurum chinense* (IC_{50} 43.22 µg/ ml), *Trillium pendulum* (IC_{50} 49.82 µg/
205 ml), and *Rheum palmatum* (IC_{50} 49.82µg/ ml). Among these four extracts, *Terminalia chebula* was the
206 most potent and therefore, further studies were performed using this plant extract.



207

208 **Figure 1**. Schematic diagram of high throughput screening for 900-plant ethanol extracts (EE) to
209 identify and rank natural lactate efflux inhibitors in N2-A cancer cells. N2-A cellular lactate production of
210 treated cells was compared to untreated normalized average % control total lactate production within 4
211 h of incubation with each extract. Extracts indicating an IC_{50} <1000 µg/ml were rescreened at lower
212 concentrations (500, 100, and 50 µg/ml). According to the IC_{50}s, the potent plant extracts were
213 categorized into 4 levels, and 4 plant extracts were the most potent (IC_{50}s < 50 µg/ml) and identified as
214 Bupleurum *chinense, Rheum palmatum, Terminalia chebula, and Trillium pendulum.*
215

Table 1. The effect of ~~900~~ top ethanol plant extracts as lactate efflux inhibitors in N2-A cells. Cells were exposed 4h to different concentrations of the plant extracts. Compared to lactate production in control cells at the highest dose (1000 µg/ ml) , 785-plant extracts were not active. The other plant extracts were categorized according to their potency as following: 62 extracts (500 µg/ml < IC_{50} < 1000 µg/ ml) and ranked as the lease potent, 43 extracts (100 µg/ml < IC_{50} < 500 µg/ml), 6 extracts (50 µg/ml < IC_{50} < 100 µg/ml), and 4 ethanol plant extracts (IC_{50} < 50 µg/ml) and considered as the most potent.

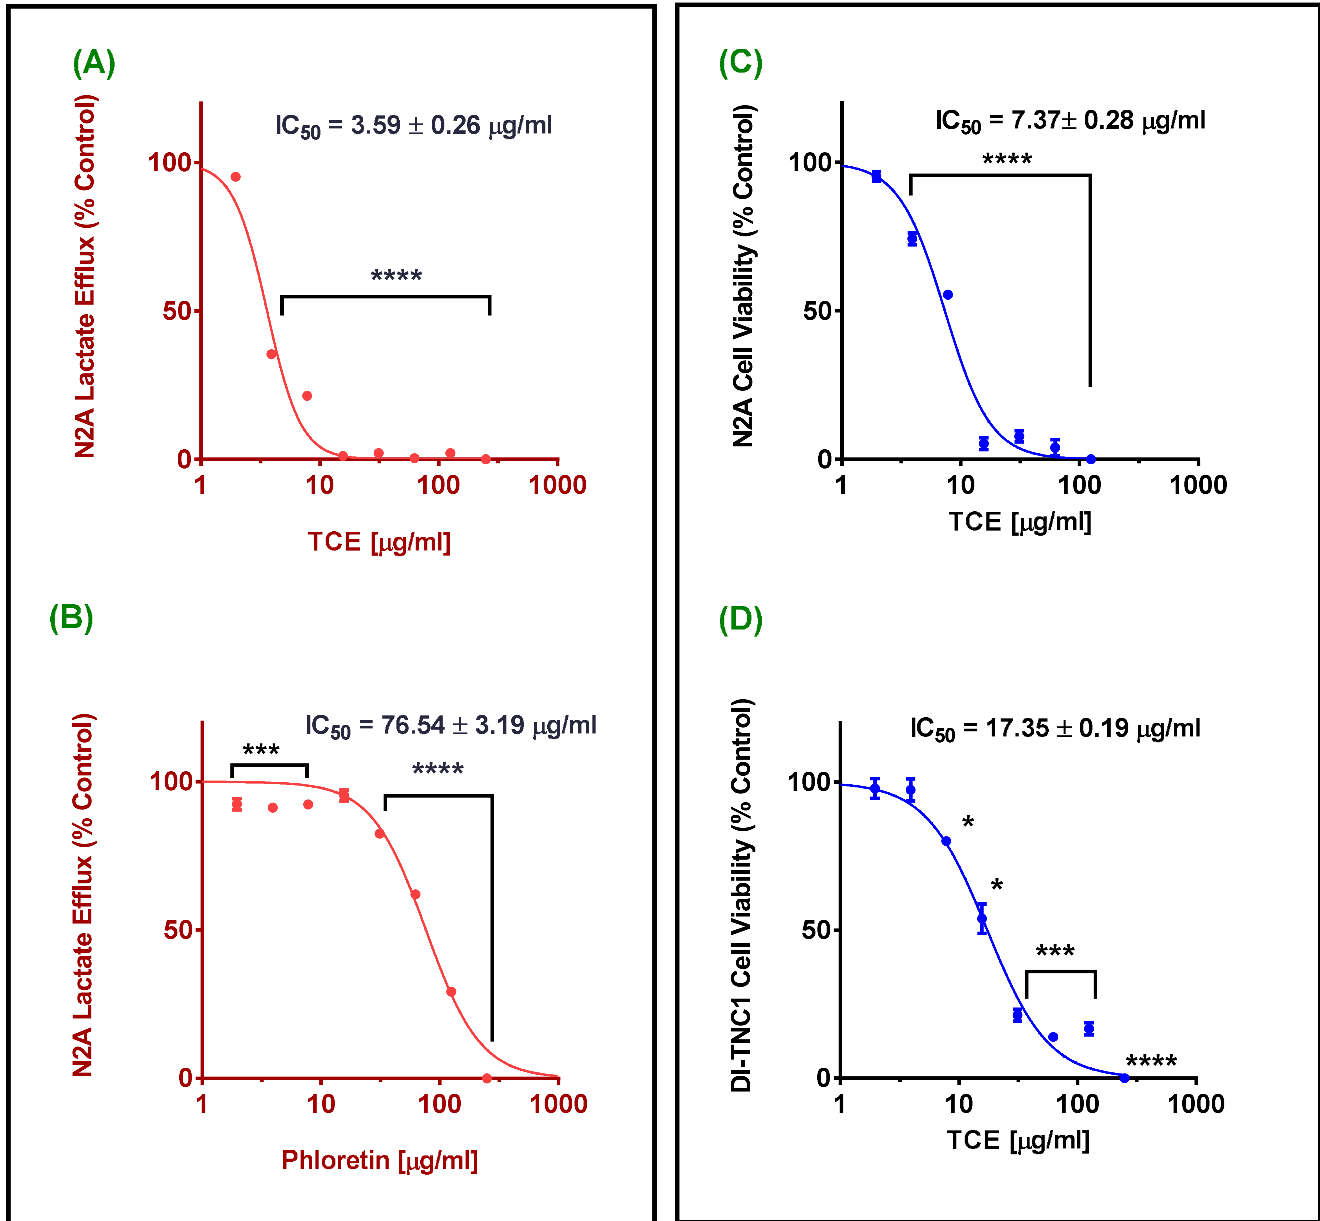
3.2 TCE Lactate Efflux Inhibition Potency

To determine **TCE** potency, we conducted dose-response studies for lactate efflux changes in N2-A cells supernatant. Lactate production was inversely proportional to the increased **TCE** concentrations. Inhibition of lactate efflux was highly significant ($P = 0.0001$), giving IC_{50} value of 3.59 ± 0.26 µg/ml (Figure A). Lactate efflux inhibition was less than 10% in N2-A cells treated with a-cyano-4-hydroxycinammic acid (CHC), at the highest tested concentration (250 µg/ml = 1.32 mM). Meanwhile, phloretin induced highly significant effect ($P< 0.0001$) with IC_{50} 76.54 ± 3.19 µg/ml (279.07 µM). Compare to the calculated IC_{50} of **TCE**, phloretin was less potent by 21.32 fold (Figure 2B). Similarly, the dose - response of the cytotoxicity studies performed using N2-A cells vs. DI-TNC1 primary cells to assess the safety of **TCE** (Figure 2 C and D). The data obtained indicated a significant inverse relationship between the viability and the tested concentrations in both cell lines ($P = 0.0001$). Noticeably, **TCE** was 2.35 fold less potent in the primary cells (IC_{50} of 17.35 ± 0.19 µg/ml) compare to N2-A cells (IC_{50} of 7.37 ± 0.28 µg/ml).



246

247

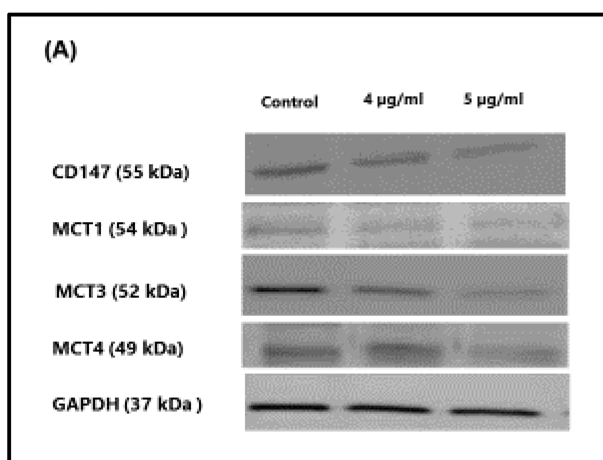
248

249 **Figure 2**. Effect of *Terminalia chebula* (TCE) on lactate efflux and cell viability. (A) and (B) are lactate
250 production profile of N2-A cells after 4 h exposure to different concentrations of TCE and phloretin,
251 respectively (C) and (D) are cytotoxicity profile of N2-A and DI-TNC1 cells after 24 h exposure period to
252 different concentrations of TCE. Statistical analysis of all studies was presented as the mean ± SEM
253 from the average of two independent experiments, n=4 each. IC_{50}s are average of two independent
254 studies sigmoidal curves. The significance of the difference between controls vs. treated cells was
255 determined using a one-way ANOVA followed by Dunnett's multiple comparisons test. Significance of
256 difference between control and treatment is considered at *$P = 0.05$, *** $P = 0.001$, and **** $P = 0.0001$

257

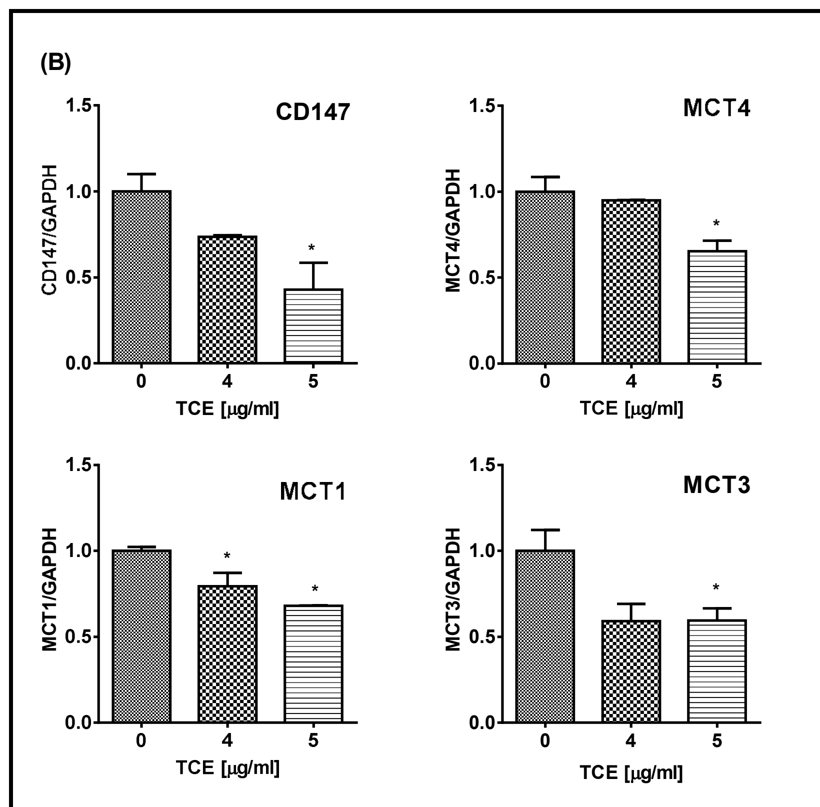
258 **3.3. TCE Reduces MCTs and CD147 Expression**

259 To understand the mode of action engaged in lactate efflux inhibition we performed Western
260 blotting for N2-A cell lysates and evaluated protein expressions of monocarboxylate transporters and
261 their chaperone CD147 after 4 h exposure to different concentrations of **TCE**. Antibodies detected the
262 different MCTs, an indication of their presence in N2-A cell line (Figure 3A). Moreover, at the highest
263 tested dose 5 µg/ml, **TCE-**induced a significant decrease in protein expression ($P = 0.05$), giving 57%
264 reduction in CD147; 35% reduction in MCT4 ; 32 % reduction in MCT1; and 41% reduction in MCT3
265 expression (Figure 3 B).



266

267



268

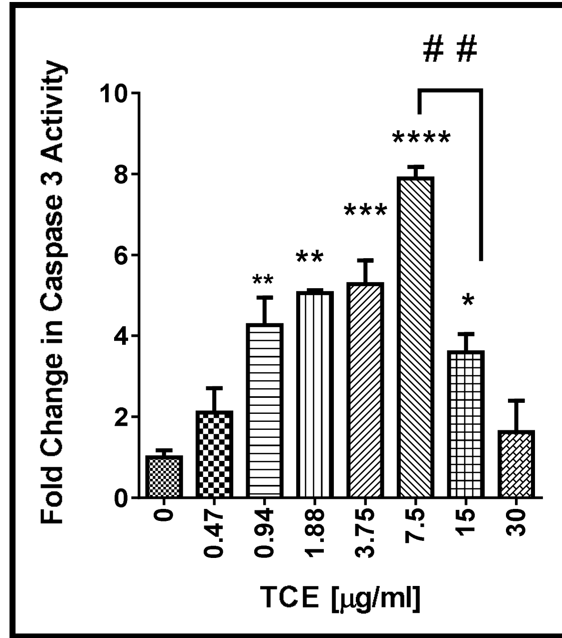
269 **Figure 3.** *Terminalia chebula* extract (TCE) effect on the expression of monocarboxylate transporters
270 (MCTs) and their chaperone CD147 in N2-A cancer cells after 4h treatment with concentration range 0
271 to 5 µg/ml of TCE. (A) Indicates the presence of all candidates as detected by their molecular weight
272 compared to the standard protein. The decrease in band intensities appeared precisely at 5 µg/ml, and
273 loading consistency was confirmed by GAPDH. (B) Data obtained from two independent studies
274 showed a significant decrease in protein expression in all candidates at 5 µg/ml. Statistical analysis
275 was presented as the mean SD from the average of two independent experiments. The significance of
276 the difference between the control and treated cell lysates was determined using one-way ANOVA
277 followed by Dunnett's multiple comparisons tests. The significance level was set at $^*P = 0.05$.

278

279 **3.4. TCE Induces Apoptosis, Morphological Changes, and Activates Caspase 3 in N2-A Cells**

280 The change of caspases 3 activity was used as a marker for apoptosis and cell death that might
281 be attributed to lactate efflux inhibition. Cell apoptosis was measured in N2-A cells after 4 h exposure
282 to **TCE.** The results show that a significant increase in caspase 3 activity, in a dose - dependent
283 manner, was detected in the cell lysates (Figure 4). The significant difference between treated and
284 control cells was detected at 7.5 µg/ml ($P = 0.0001$), giving almost 8 folds' increase in caspase activity
285 relative to the control cells. Also, a significant decrease was also obtained ($^{\#\#}$ P = 0.01) at a higher
286 dose (15 µg/ml).

287



288 **Figure 4.** Activation of caspase 3 in N2-A cells by *Terminalia chebula* (TCE). Caspase 3 was measured
289 in the cell lysates of two independent studies with n=3 and expressed as fold increase compares to the
290 control. The significance of the difference between treated cells vs. control. Significance is considered
291 at * P = 0.05, ** P = 0.01, *** P = 0.001, **** P = 0.0001, and ## P = 0.01.
292

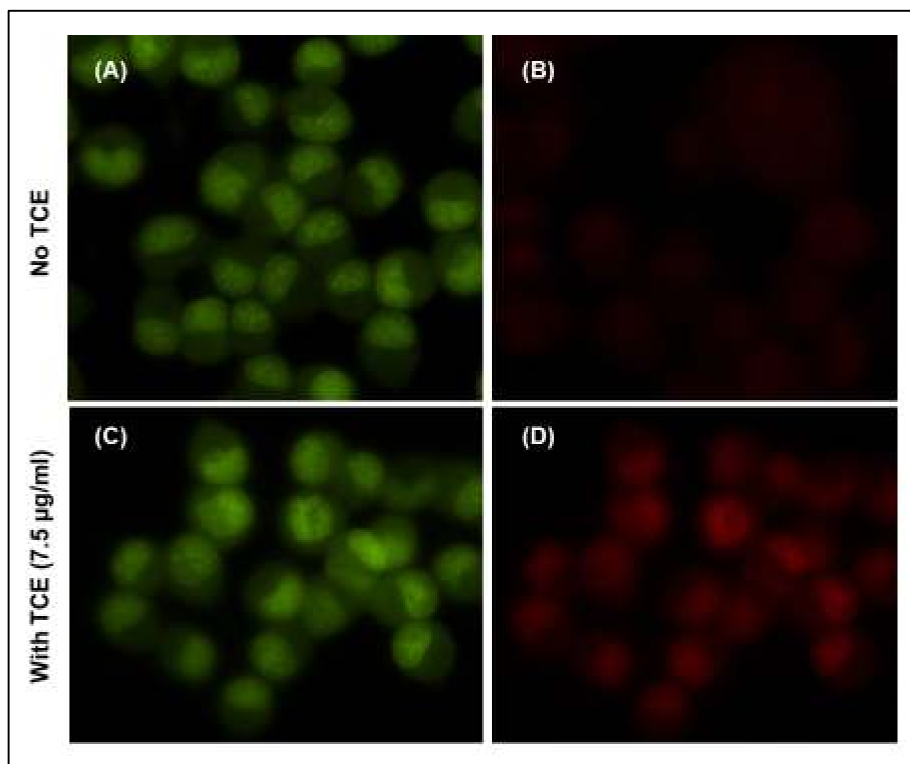
293 The apoptosis-related morphological changes of **TCE** were further investigated using acridine
294 orange/ethidium bromide fluorescence assay. Untreated cells appeared with uniformly green nuclei
295 (Figure 5 A) while different degrees of early and late apoptotic features appeared clearly in cells treated
296 with 7.5 μg/ml (Figure D). Early apoptotic cells appeared with bright green dots in the nuclei, while
297 chromatin condensation and nuclear fragmentation were detected in the late apoptotic stage as cells
298 lose the membrane integrity and incorporate a red color - ethidium bromide.

299

300

301

302 Acridine orange Ethidium bromide

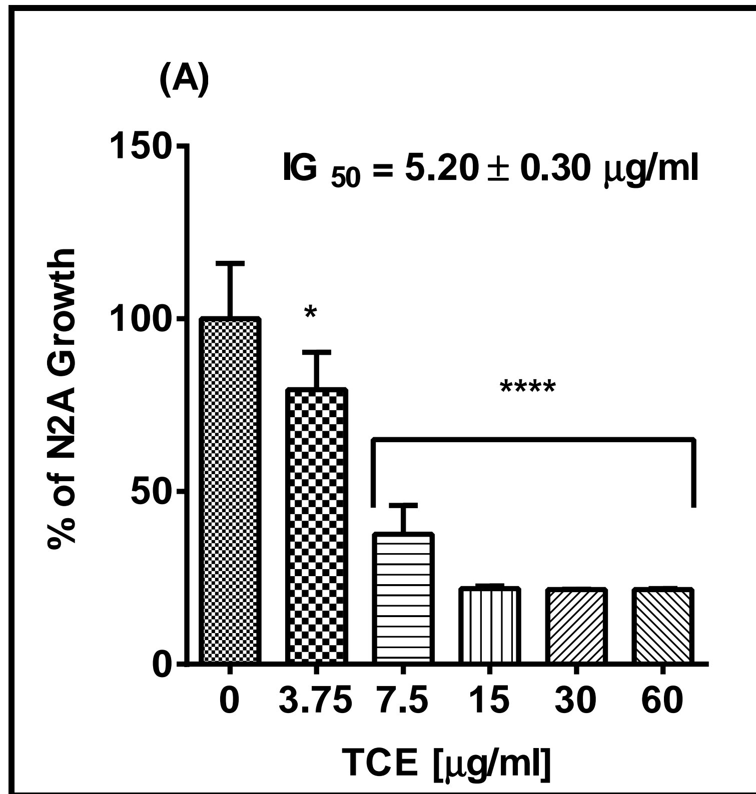


303

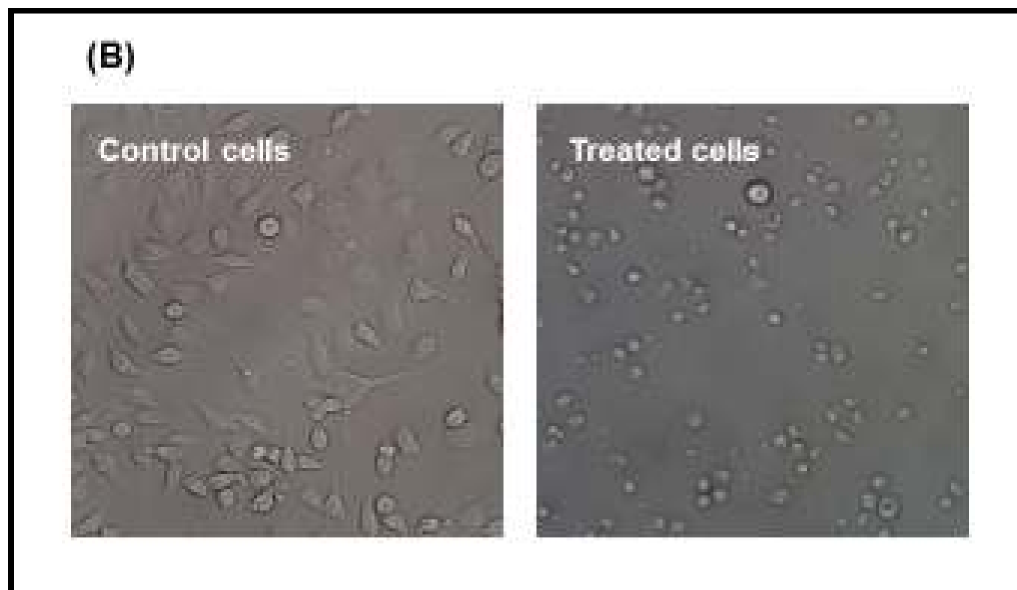
304 **Figure 5.** Apoptotic effect of *Terminalia chebula* (TCE) in N2-A cells. (A) Control cells stained with
305 acridine orange and appeared with uniform green - stained nuclei. (B) Control cells stained with
306 ethidium bromide. (C) Acridine orange - stained cells treated for 4 h with 7.5 µg/ml of TCE appeared
307 with bright dots at the nuclei as symptoms of early apoptosis. (D) Ethidium bromide stained cells
308 treated for 4 h with 7.5 µg/ml of TCE appeared red color and fragmented and condensed nuclei were
309 detected in late apoptotic cells. Microscopic magnification was 40X.
310

311 **3.5. The Growth Inhibition Effects of TCE**

312 The impact of **TCE** on N2-A cell growth was evaluated at 48 h exposure period. **TCE** decreased
313 cell proliferation in a dose-dependent pattern with a highly significant reduction in cell proliferation (P =
314 0.0001) was observed at the tested concentration of 7.5 µg/ml and above, giving IG_{50} = 5.2 ± 0.30 µg/ml
315 (Figure 6 A). Remarkably, almost 76% reduction in cell proliferation was obtained at 15 µg/ml of **TCE**
316 and remained consistent at the other higher doses. Also, Phase-contrast microscopy revealed that
317 treated cells decreased in numbers and appeared round with shrunk size compared to the control
318 (Figure 6 B).



319



320

321 **Figure 6.** Effect of *Terminalia chebula* (TCE) on N-2A cell growth and morphology. (A). Cell growth
322 activity of N2-A treated for 48h with different concentrations of TCE. Statistical analysis is presented as
323 the mean ± SEM of two independent experiments with n=4. The significance of the difference between
324 treated cells vs. control was determined using one-way ANOVA followed by Dunnett's multiple
325 comparisons test. The IG_{50} is the average of two studies sigmoidal curves. Significance is considered at
326 *P = 0.05, and **** P = 0.0001. (B). Phase contrast of N2-A cells treated for 48 h with or without 15.0
327 µg/ml of TCE and microscope magnification was 20 x objective magnification.

328

329 ## 4. DISCUSSION

330 Lactate efflux is critical for cancer cell metabolism and proliferation. Thus, targeting lactate
331 produced by cancer cells was the primary goal of this study. Extracts of 900 plants were screened for
332 lactate efflux inhibition in N2-A neuroblastoma cells that are characterized by a high metabolic rate and
333 excess lactate efflux [22]. The extract of *Terminalia chebula* (**TCE**) plant was the most potent extract as
334 lactate efflux inhibitor. The plant, Terminalia chebula Retz, belongs to the family Combretaceae and
335 also called black Myrobalans (English) and Harad (Hindi). The full grown plant is a tall tree up to 80 feet
336 in height, is native to India, known as the 'King of Medicine' since it was used in healing many diseases
337 such as heart diseases, asthma, gout, bleeding piles, vomiting, diarrhea, ulcers, sore throat, and
338 dysentery. [17]. .The extensively studied *Terminalia* species indicate that this plant has a wide
339 spectrum of medicinal effects. The plant was reported to have an antimicrobial [23], antiviral,
340 antimalarial and antifungal [24], antiprotozoal [25], anti-inflammatory, anti-arthritic [26], antidiabetic [27],
341 hepatoprotective [28], antioxidant [29], antianaphylactic [30]-, antimutagenic [31], and anticancer [32]
342 [33-36] effects. Several studies have also indicated that the methanolic and water extracts of **TCE** have
343 an inhibitory action on the human immunodeficiency virus [37] and immunomodulatory action [38].
344 Additionally, a recent study using the rat pheochromocytoma (PC12) cell line indicated that the extract
345 of the dried ripe fruit has a neuroprotective effect against ischemia related damage [39].

346 Since our primary concern in this study is to evaluate the levels of extracellular lactate as an
347 indication of functional MCTs, we examined the potency of **TCE** comparing to the well- known lactate
348 inhibitors phloretin and CHC [40, 41]. The obtained results indicate that 50% of lactate efflux inhibition
349 in N2-A cell was obtained when cells were treated with 279.07 μM of phloretin. The obtained results are
350 in agreement with the previously reported study that found 300 μM of phloretin inhibited lactate
351 transport in erythrocytes [42]. Interestingly, our data showed a remarkable effect of **TCE** over phloretin.
352 On the contrary, current data did not show a significant inhibitory effect of CHC at the highest tested
353 concentration. In spite of the reported effects of CHC as an MCT1 selective inhibitor [43] by affecting
354 the expression of MCT1 [3], no sufficient information about the impact of CHC on N2-A cells. However,
355 our results agree with previous studies that 5mM of CHC did not inhibit lactate efflux in glial cells [44]
356 and should be at least 10 mM to inhibit MCT efflux in malignant gliomas [45].

357 Current literature did not report the selective cytotoxicity of **TCE** among different cancer cell
358 lines. However, *Terminalia chebula* was reported as a safe chemopreventive drug within the
359 recommended Ayurvedic specifications [46]. Also, in an in vivo study, *Terminalia chebula* dried fruits

360 water extract was found to cause neither acute nor chronic toxicities when tested in male or female rats
361 [47]. These data confirm our cytotoxicity study on DI-TNC1 primary cell line.

362 To explore the mechanism of action of lactate efflux inhibition by **TCE**, we examined MCT
363 transporters as important pH regulators in high glycolytic solid tumors that mediate lactate
364 transportation across the plasma membranes [48]. Also, the suppression of monocarboxylate
365 transporters is considered the first step in apoptosis [49]. Lactate efflux through MCT4 was previously
366 reported [2]. However, MCT1 and MCT3 might facilitate lactate passing through the plasma membrane
367 under certain conditions [16] [17]. On the contrary, MCT2 expression is reduced in highly glycolytic
368 cancer cells [50] since it involves in lactate uptake under normal metabolism [51]. Thus, Western
369 blotting was performed to evaluate the expression of MCT1, MCT3, and MCT4 in treated N2-A cells.
370 Furthermore, the expression of, a chaperone to some MCTs was also studied. CD147 is a
371 multifunctional protein and also known as basigin, controlling and regulating energy metabolism of
372 cancer cells [52]. Importantly, it is necessary for MCTs stabilization and expression at the cell
373 membrane [53]. Accordingly, disabling MCTs through disrupting their association with CD147 is
374 considered one of the novel approaches to inhibiting MCTs.

375 To our knowledge, this is the first study to report on the expression of MCT1, MCT3, and MCT4
376 and the chaperone CD147 in neuroblastoma N2-A cells. However, previous studies found similar
377 expression of MCT1 in human neuroblastoma cell lines (IMR32, NGP, and SK-N-SH) [22] and MCT4
378 expression was higher in MDA-MB-231 [54]. Although all proteins under investigation showed a
379 significant decrease in their expression at the highest tested dose of TCE, the highest reduction was
380 observed in CD147 expression. Considering all these findings, we might attribute **TCE** inhibition of
381 lactate efflux to the reduction of CD147 expression more than MCT4 itself. In other words, **TCE** may
382 have inhibited MCT4 function indirectly through CD147 suppression. The role of MCT3 in cancer cells
383 is poorly studied. However, a previous study on the retina of the rat reported MCT3 as lactate efflux
384 transporter [55]. Interestingly, the decrease in MCT1 expression might be another reason for the
385 insignificant lactate efflux inhibitory effect of CHC in N2-A cells, an interpretation that agrees with a
386 previous study since CHC exerts an inhibitory effect on tumors cells expressing MCT1 at the plasma
387 membrane [15].

388 In the current study, apoptotic effect of **TCE** was confirmed by caspase 3 activity. Caspase 3 is
389 a cysteine protease, and its activation is considered a critical step in cell apoptosis [56]. Our findings
390 are in agreement with earlier studies indicated that quercetin isolated from the fruits of *Terminalia*
391 *spp*[SM1] was found to induce apoptotic effects in N2-A cells [57], chebulagic acid was also reported to
392 induce apoptosis in COLO-205 cells [58]. Similarly, apoptosis was reported in human breast cancer
393 MDA-MB-231 treated with pentagalloylglucose and quercetin [59] and HL-60 cells treated with

394 ellagitannins [60]. Current proliferation study was comparable to the previous study that showed a
395 decrease in cell proliferation upon lactate efflux inhibition in breast cancer cells [61]. Despite the
396 differences in the method of extraction, as well as the cell line, the growth inhibition effect was profound
397 by *Terminalia chebula* when tested in various cell lines [32].

398 **5. CONCLUSION**

399 Out of 900 ethanol plant extracts screened, Terminalia chebula ethanol extract was found to be
400 the most potent lactate efflux inhibitor with the ability to inhibit Chaperone CD147 expression and
401 impact the function of monocarboxylate transporters. Furthermore, TCE has growth inhibition and
402 apoptotic effects. The obtained results indicate that the plant *Terminalia chebula* constituent(s) may
403 contain new targets for the management of neuroblastoma.
