3 **HIV-positive individuals: Exercise, Yoga and Quality of life**

4

5 **Abstract:**

Background: Human immunodeficiency virus (HIV) infection worsens the frailty of individuals
making them vulnerable and compromising their quality of life. Auxiliary to this, considerable stigma
and social rejection are associated with HIV infection contributing to anxiety and depression.
Research has verified the beneficial effects of exercise; yoga on the physical and psychological health
across populations and therefore this study was conducted to assess its effects in HIV positive
individuals.

Methodology: 60 HIV patients were divided into 3 groups randomly; Group 1 (medical treatment),
Group 2 (aerobic training) and Group 3 (yoga training). Intervention was started after informed
consent and ethical approval for 6 weeks. Outcome measures used were BMI, Six-minute walk test,
Hamilton Anxiety scale, and SF-36. The data was then calibrated and analyzed by ANOVA and ChiSquare t-Test

17 Results: After 6 weeks of treatment, the BMI, anxiety levels and quality of life tested showed a 18 significant change in Group 2 and 3. Also, there was a considerable decrease in anxiety among 19 patients in Groups 1 and 2. Quality of life was much better in Groups 2 and 3 compared to Group 1 20 Conclusion: Exercises significantly improve physical and psychological health status, well-being and 21 quality of life in HIV positive individuals. Aerobic training showed superior developments than yoga 22 and can be used as an adjunct to medical line of treatment.

Keywords: HIV positive patients, Exercise training, Aerobics, Yoga, Physical wellbeing,
Psychological Health, Quality of life.

- 28 **Introduction:**

29 Human immunodeficiency virus (HIV) and Acquired immune deficiency syndrome (AIDS) is a 30 significant threat to health and well-being of human population. HIV is a retrovirus that progressively 31 lowers the body's CD4+ cell counts and impairs the immune system¹. With 35.3 million people 32 globally and 2.6 million people in India living with HIV till the year 2012, it is of serious concern. 33 The recent advances in the medical field are complementing early detection of HIV patients by 34 effective screening and diagnosis. Highly active antiretroviral therapy (HAART) has increased the life span of the HIV infected patient by many folds.^{2,3,4,5,6}These drugs slow the rate at which the virus 35 36 multiplies and promote favorable virological control, which significantly decrease the morbidity and 37 mortality associated with HIV. Although the introduction of HAART has improved longevity of the 38 HIV patients, the cost of improved immune function and life expectancy have been associated with 39 the development of several metabolic and cardiovascular symptoms as severe as lipodystrophy, 40 dementia, depression, insomnia, Nervous system disorders – demyelination, neuropathy, neurosensory 41 and neuromuscular disorders, Toxic effects of chemotherapeutic medical agents to other co-42 morbidities like muscle pain, fatigue, multiple joint aches, myopathies, endocrine dysfunctions, 43 physical inactivity and other psychogenic implications. These individuals are now living longer, but 44 with more chronic disease. ^{7, 8,9,10} 45 The increased chronicity of HIV infection has been mirrored by increased prevalence of disablement 46 in the HIV positive individuals. Rusch et al in their study established that the treatment of these 47 individuals should be done holistically by management of impairments (problems with body function 48 or structure – pain, weakness), activity limitations (difficulties in executing daily living activities) and 49 participation restriction (social involvement difficulties, inability to work), thus improving their 50 functional performance.¹¹Exercise has been proved to have many potential prophylactic benefits 51 associated with improved lean body mass, strength, psychological status and cardiovascular fitness. 52 Participation in an exercise program may be an important adjunct to pharmacological treatment to 53 improve the metabolic and morphological features in HIV/AIDS. Researchers have identified the 54 benefits of Aerobic exercise training and yoga amongst HIV positive patients but, very few studies have explored the benefits of these with respect to quality of life. ^{12,13,14,15} 55

56 Yoga has been said to play an important in the rehabilitation of patients with HIV.¹⁶ Joseph and Nair,

57 in their study observed a trend of increase in the CD4 counts following a yoga intervention.¹⁷

58 Similarly, integrated yogic practice was found to reduce depression and boost immunity in HIV

59 infected individuals by Naoroibam and Metri.¹⁸

- 60 Therefore, this study was conducted to investigate the effects of exercises (aerobic and yoga) on the
- 61 subjective well-being of HIV positive individuals.
- 62

63 **Methodology:**

64 60 HIV positive subjects between the age group of 20 to 40 years (mean age 33.25) with CD4 65 lymphocyte counts between 200 and 500 cells/mm³ were included from the HIV clinic of the 66 medicine outpatient department of a public sector hospital. On receiving the approval of the 67 institutional ethics committee, written consent from each patient was obtained prior to 68 commencement of the study. After the initial screening, patients without signs of opportunistic 69 infections and co-morbid conditions were included and randomly allocated into 3 groups: Group 1 70 (medical line of treatment), Group 2 (aerobic exercises) and Group 3 (yoga). The study was single 71 blinded. After the study completion, this trial was registered with the Clinical Trials Registry – India 72 (CTRI).

73

74 **Outcome measures used in the study were:**

• Body Mass Index (BMI)^{19: measured} with weight and height of an individual.

Exercise tolerance testing²⁰: was conducted using a 6-minute walk test. Before starting, the
 basal values for blood pressure, heart rate and respiratory rate were recorded. Patients were
 encouraged to walk as far as possible and the distance was noted. The values post test were
 documented and compared between the 3 groups.

Hamilton Anxiety Scale (HAS) ²¹: is a series of semi-structured questions related to symptoms of anxiety. The interviewer then rates the individuals on a 5point scale for each of the 14 items. 7 items of the scale specifically address psychic anxiety while the remaining 7

83	tackle somatic anxiety. For the 14 items the score ranges between $0 - 4$. $(0 - no anxiety, 1 - $
84	mild anxiety, 2 - moderate, 3 - severe and 4 - grossly disabling anxiety) The total anxiety
85	score ranges from $0 - 56$.
86	• SF-36 Scale ^{22, 23} : is a set of generic, coherent and easily administered quality of life
87	questionnaire. This multipurpose, short-form health survey has 36 questions yields an 8point
88	scale profile of functional health and well-being along with psychometrically based physical
89	and mental health summary measures. Each question is directly transformed into a 0-100
90	scale, the lower the score the more disability. The 8 domains include Vitality, Physical
91	functioning, Bodily pain, General health perceptions, Physical role functioning/limitations,
92	Emotional role functioning/limitations, Social functioning and Mental health. The strength of
93	the SF-36questionnaire is that, it's a concurrent measurement of mental and physical health
94	status both.

General Marching, High step marching, Brisk walking, Stepping and Jogging covered the Aerobic phase while the cool down phase consisted of slow movements, breathing exercises and relaxation in supine lying. Group 3 (yoga): Patanjali described the yogic practice in the form of eight limbs (Ashtanga Yoga) the main three parts of yoga are- exercise, breathing and meditation ²⁵ . This group performed asana and pranayama in 30 minutes, 3 times per week for 6 weeks. Asanas in yoga are physical postures which

- the organs and systems of the body, promoting positive health and overall well-being²⁶. The asanas
- 112 were performed in standing (Tadasana, Trikonasana, Parvatasana and Ekhastapadasana), sitting
- 113 (Padmasana, Vajrasana, Yogmudrasana and Gaumukhasana) and prone (Shalabhasana, Bhujangasana,
- 114 Naukasana and Dhanurasana) positions.
- 115 Pranayama or breath control is aimed to achieve organized breathing and reduce symptoms of
- anxiety. The session is ended with a pranayama. It incorporates breathing practices aimed at bringing
- into utilization all the lobes of the lungs for continuous and rhythmic breathing. The patients are, thus,
- 118 subjected to deep relaxation after physical postures, that in turn reduces anxiety.²⁶
- All the patients (20 in each group) remained in the study for a follow up of 6 weeks and responded
- 120 uniformly to the treatment. The ANOVA and Chi Square test was used for statistical analyses.
- 121

122 **Results:**

123 Table 1: Comparison of changes in mean BMI after treatment between the groups.

Duration in Weeks	Mean BMI (kg/m2)		
	Group 1	Group 2	Group 3
Baseline	21.80 + 1.55	20.69 + 1.20	21.32 + 0.83
At 6 weeks	21.59 + 1.43	21.25 + 1.30	21.37 + 0.88
Difference	*-0.21 <u>+</u> 0.36	*0.56 + 0.37	0.064 + 0.15

124

125 Table 2: Comparison of changes in mean 6-minute walk distance after treatment between the groups.

	Mean 6 MWD (meters)		
Duration in Weeks			
	Group 1	Group 2	Group 3
Baseline	411.00 + 52.05	431.00 + 38.47	405.28 +42.58
At 6 weeks	414.00 + 59.06	514.44 + 52.27	434.44 + 45.27

Difference	3.00 + 10.44	*83.44 + 20.52	*29.17 + 9.12

127 Table 3: Comparison of changes in mean HAS scores after treatment between the groups.

Duration in Weeks	Mean HAS scores		
	Group 1	Group 2	Group 3
Baseline	20.70 + 6.75	9.72 + 7.51	15.61 + 6.45
At 6 weeks	19.00 + 7.73	12.89 + 5.50	11.39 + 4.29
Difference	*-1.70 + 2.39	*-6.83 + 2.57	*-4.22 + 3.34

128

129 Table 4: Comparison of changes in mean physical functioning scores after treatment between the

130 groups.

Duration in Weeks	Mean Physical functioning scores		
	Group 1	Group 2	Group 3
Baseline	60.00 + 16.58	65.12 + 23.25	57.71 + 23.89

Difference	0.50 + 6.05	*21.94 + 13.84	*3.33 + 5.69

136

137 **Discussion:**

138 This is a prospective, randomized study aiming to analyze the effects of exercises (aerobic and yoga)

139 on aerobic function, quality of life and the psychological status and well-being in HIV positive

140 individuals. Active participation in the management of their disease with a strong sense of personal

141 control is important for optimal health outcomes^{11, 25}. HIV patients experience psychological distress

142 that impacts their quality of life and disease progression which reduced on introduction of aerobic

143 exercises and yoga.^{27, 28}

The practice of Yoga can provide many physical, emotional, mental and spiritual benefits. On a physical level, Yoga poses (asana) can increase flexibility, strength, balance and coordination. It helps stabilizing emotions. It also helps to reduce anxiety, stress and is easily adapted to one's level of energy and stamina^{29, 30}. The meditative aspect of yoga is often achieved through an individual's mental focus on asana and prana. Pain reductions are achieved by regulating the pain gate mechanism through the secretions of natural endorphins and encephalins. Pranayama also causes muscles to relax, reduces tension achieving calmer, slower respiration aiding in pain management^{31, 32}. 151 It has been seen that the optimum intensity to improve aerobic capacity is about 70% of maximum 152 heart rate that is equivalent to about 50-55% of maximum aerobic capacity for young adults³³. 153 Considering HIV patients with known issues like easy fatigability, reduced stamina, musculoskeletal 154 pain, lack of exercise and other systemic symptoms, the intensity used in our study was 40-50%³⁴. It 155 was also stated that the optimum duration for aerobic training can be 20 - 30 minutes, frequency 3 156 times per week and moreover, optimum training period found to be effective for HIV patients was of 157 6 weeks^{35, 36}.

158 As depicted in Table 1, at the end of 6 weeks, the mean BMI showed a significant change in Group 2

159 greater than Groups 1 and 3. This change in BMI could be the result of increased demand by efficient

aerobic training by patients. Aerobic exercises increase energy, appetite and a sense of well being. By

- 161 improving the nutritional status of an individual with HIV infection, aerobic exercises are shown to
- 162 improve the patient's overall health³⁷.

Similarly, the 6-minute walk distance showed a significant increase in Groups 2 and 3 compared to Group 1 as illustrated in table 2. Group 2 showed an increased distance compared to Group 3. Aerobic exercises condition the cardiovascular system increasing the oxygen availability to the body. Its other benefits include increased fatigue resistance, toned body, increased lean body mass and general stamina. Furthermore, yogic poses on a physical level increase flexibility, strength, balance and coordination. Hence, both these groups show significant improvements in the walk distance. Similar

169 findings were reported by O'Brien et al, Lasater and other researchers.^{29, 32, 33, 36}.

Table 3 represents the changes in the mean HAS scores. Group 2 showed a more significant decrease in anxiety than Groups 3 and Group 1. This can be attributed to the fact that exercises improve mood, physical endurance and reduces tension and fatigue. It also increases the CD4+ cell counts helping to fight infections and resulting in a sense of well being^{15, 38}. Even group 3 showed significant decreases in the anxiety levels owing to the relaxing and calming effect of the asana and pranayama^{39, 40}.

175 The SF-36 questionnaire, which concentrates on the patient's experiences, feelings, beliefs, 176 perceptions and convictions regarding their health-related quality of life during the past 6 weeks, 177 consists of close-ended structured questions. These questions relate specifically to 8 quality of life 178 indicators and 2 summary measures that revolve around both physical and mental health. As depicted

179	in Tables 4,5and 6, Group 2 shows significant variations compared to Group 3 and 1. This further
180	shows that aerobic exercise training is an important therapy to offer HIV positive individuals. The
181	improved muscle strength and endurance seem to have reduced the overall pain, discomfort and
182	fatigue. The patients were also seen to improve in their social participation owing to this. The general
183	mental health is observed to improve on account of release of the endorphins and encephalins during
184	exercises which relieve stress and elevate the mood. This study has created awareness amongst the
185	medical practitioners in our institute towards the benefits of exercises in the subjective well-being of
186	HIV positive individuals and has changed the treatment protocol which now includes exercises as
187	well.

189 **Conclusion:**

Our study indicates that both aerobic exercises and yoga individually improve the physical and psychological health status, well-being and quality of life of HIV positive patients. Thus, aerobic exercises and yoga can be administered safely in HIV positive patients as an adjunct to medical line of treatment bearing in mind the chronicity of the condition. It also illustrated that aerobic exercises produced significant improvement in BMI, exercise capacity, reduced anxiety, pain and overall general health more than yoga. Moderate intensity exercises not only improved the physical fitness but also improved the quality of life of a HIV positive individual.
