ABSTRACT

8

A field experiment was performed with BRRI Dhan 29 at Field Laboratory of Soil Science, Hajee Mohammad Danesh Science and Technology University, Dinajpur, Bangladesh. The effects of organic (cowdung) and inorganic (urea) amended N fertilizers were evaluated for NPKS contents and uptakes in grain and straw, and also for observing N use efficiency. Randomized complete block design was set for seven treatments based on recommended dose of N (RDN) @ 150 kg ha⁻¹ using cowdung and/or urea alone or their combinations. The NPK contents as well as their uptake in grain and straw were significantly affected due to different treatments while S content was insignificant. The application of recommended doses of N from urea (T_1) showed highest N content in grain (1.11%) and straw (0.71%) which was closely followed by the treatment T_6 (20% RDN from cowdung + 80% RDN from urea). The maximum P content was found from the grain and straw of T_6 treatment whereas a significant increase in the P, K and S contents were noted due to combined application of N from cowdung and urea. The NPKS uptake of grain and straw as well as total uptake (107.60 kg ha⁻¹ N, 27.84 kg ha⁻¹ P, 71.36 kg ha⁻¹ K and 25.63 kg ha⁻¹ S) were recorded maximum in T₁, followed by T_6 . The treatment T_1 yielded maximum apparent N recovery efficiency (45.06%) and agronomic N use efficiency (19.60 kg kg⁻¹) while the maximum physiological N use efficiency (43.55 kg kg⁻¹) was found in T_6 Results also suggested that the application of lower doses of urea N with higher doses of cowdung N were not useful for the N recovery due to low N supplying potentiality of manures in a single cropping season. However, the incremental rates of urea N upto 80% along with 20% cowdung N effectively increased the recovery of N in all the parameters of N use efficiency and should be applicable to optimize the need for N requirement and build up a good soil health.

1. INTRODUCTION

15 Rice is the principal carbohydrate supplying food crop for the people of Bangladesh and she is the fourth-largest rice producer in terms of area and production among the rice growing countries [1]. The 16 agriculture in Bangladesh is mainly dominated by intensive rice cultivation in favor of its geographical 17 and agroclimatic conditions but the soils experience multiple nutrient deficiencies over the years. In 18 intensive cropping system, continuous use of high levels of chemical fertilizers usually with high N 19 inputs lead to nutritional imbalance in soil, decline crop productivity and reduced N use efficiency as 20 21 well as increased N loss to the environment [2]. The farmers of Bangladesh use only about 172 kg 22 nutrients ha-1 annually (132 kg N, 17 kg P2O5, 17 kg K2O, 4 kg S, 2 kg Zn + B), as against the crop removal of about 250 kg ha-1 [3] and they are mainly concerned about the widely used urea N 23 24 fertilizer for rice cultivation. A recent estimate also showed that rice (HYV) uptake about 108 kg N, 18 25 kg P, 102 kg K and 11 kg S ha-1 from soils [4]. Considering the ecological and environment concerns 26 over the increased and indiscriminate uses of inorganic fertilizers have continued to stimulate 27 research on uses of organic materials as sources of nutrients [5]. Use of organic matter as a source of 28 plant nutrients increases the fertilizers use efficiency and makes soil living. Nitrogen is 29 characteristically the nutrient of most concern because of its enormous impact on cereal crop yields

Keywords: Cowdung, urea, NPKS, uptake, nitrogen use efficiency, rice etc.

30 including rice. Manure is one of the most important N sources in paddy rice systems although it poses a countless challenge in meeting rice N requirement. Generally, manure amended rice systems 31 32 historically been used for its N use efficiency improvement and animal waste recycling. Nitrogen 33 release from manure is relatively slow compared to chemical N fertilizer like urea, and may mismatch 34 the N requirement for rice growth, especially during the mid or late rice growth period. Many agroecologists have focused that manure should be applied as basal fertilizer and combined with urea 35 36 or other fast released chemical N fertilizers as topdressing [6,7]. The split application of N might 37 provide a compromise between traditional and modern production systems which would improve both 38 soil micro environment and N use efficiency [8]. So, selection of adequate amounts of N from organic 39 and inorganic sources is one of the best solutions for sustainable rice cultivation. Cowdung is a 40 potential source of organic manure in Bangladesh and extensively used in the vegetables cultivation. 41 The application of cowdung in rice fields as a nutrient source may reduce the requirement of chemical 42 nitrogenous fertilizers, but the question has not been examined sufficiently for a wide array of soil and 43 variety. It is also important to look beyond the immediate crop needs of highly demanding N nutrition 44 during growth in order to optimize the uptake and use efficiency from organic and inorganic sources. 45 Therefore, the present study was carried out to evaluate the effects of nitrogen either from urea or 46 cowdung along with their combinations on the changes of nutrient contents, uptake and use efficiency 47 by BRRI Dhan 29.

48

49 2. MATERIAL AND METHODS

51 2.1 Experimental site and soil

52

50

The experiment was set up at the Soil Science Field Laboratory, Hajee Mohammad Danesh Science and Technology University (HSTU), Dinajpur during the boro season (January to May 2015). The site was under the Old Himalayan Piedmont Plain (AEZ 1) and the soils belong to Ranisankail series having sandy loam texture. The soil was characterized by slightly acidic in nature (pH = 6.56) with OC (0.34%), total N (0.02%), available P (11.24 ppm), exchangeable K (0.13 me 100⁻¹ g), exchangeable Ca (1.26 me 100⁻¹ g), exchangeable Mg (0.51 me 100⁻¹ g), available S (35.47 ppm), available Zn (0.74 ppm), available B (0.23 ppm), and CEC (5.5 me 100⁻¹ g).

61 2.2 Treatments and design

There were seven treatments consisting different combinations of recommended dose of N (N_{150}) 62 63 either from organic and/or inorganic sources (cowdung and urea used as organic and inorganic 64 sources, respectively). The treatment combinations were T₀: Control (no nitrogen), T₁: 100 % RDN from urea, T2: 100% RDN from cowdung, T3: 80% RDN from cowdung + 20% RDN from urea, T4: 65 66 60% RDN from cowdung + 40% RDN from urea, T₅: 40% RDN from cowdung + 60% RDN from urea, and T₆: 20% RDN from cowdung + 80% RDN from urea. All the treatments also received 67 recommended doses of other nutrients on soil test basis (P₂₀K₆₅S₁₈Zn_{1.3}) through TSP, MOP, gypsum 68 69 and ZnSO₄, respectively. The treatment wise required nitrogen from cowdung was calculated on the 70 basis of 0.78% N content of well decomposed dried cowdung. The experiment was laid out in the 71 randomized complete block design (RCBD) with four replications following the net plot size of 15 sq. 72 m (5m x 3m). The full doses of cowdung as per treatments were added 15 days before transplanting. 73 The full doses of TSP, MP, Gypsum, Zinc sulphate were applied during the final land preparation. 74 Urea was applied in three equal splits: the first split after 7 days of transplanting, the second split as 75 top dressing after 30 days of transplanting while third one after 60 days of transplanting (before 76 panicle initiation stage). The standard procedure was followed for transplantation as well as other 77 intercultural operations. After recording the yield, grains and straw samples from each unit plot were 78 collected for analysis of nutrient contents.

- 80 81

2.4.1 Preparation of plant samples

2.4 Analyses of nutrient contents in plant samples

82 83

Both the grain and straw samples were dried in an oven at 60°C for 24 hours and then grounded by a
 grinding mill. The prepared samples were kept in desiccators until analyses.

87 2.4.2 Determination of total nitrogen

88

89 Well ground 0.1 g oven dry samples were taken in kjeldahl flasks containing 1.1 g catalyst mixture (K₂SO₄ CuSO₄.5H₂O: Se = 100: 10: 1), 3 ml 30% H₂O₂ and 5 ml conc. H₂SO₄. The flasks were 90 swirled and allowed to stand for 10 minutes and heated at 380 °C until the digest became clear and 91 92 colourless. After cooling, the content was diluted with water and made the volume of 100 ml. Then, 93 40% NaOH was added with the digests for distillation and the evolved ammonia was trapped in 4% 94 H_3BO_3 solution having 5 drops of the mixed indicator [bromocressol green ($C_{21}H_{14}O_5Br_4S$) and methyl 95 red ($C_{10}H_{10}N_3O_3$) solution]. Finally, the distillates were titrated with the standard 0.01 N H_2SO_4 until the 96 colour changed from green to pink [9]. A reagent blank was also prepared in the same way for 97 accuracy in analysis. 98

99 2.4.3 Determination of P, K and S

100

Plant samples (0.5 g) were digested by using 10 ml of diacid mixture (HNO₃: HClO₄ = 2: 1) into 100 ml 101 102 kjeldahl flasks. After leaving for overnight, the flasks were heated slowly upto 200 °C until the 103 contents became sufficiently clear and colourless. After cooling, the digests were diluted by distilled 104 water to make 50 ml in a volumetric flask. The digests were then filtrated and used for P. K and S 105 determination. 1 ml digest from grain samples and 2 ml digests from straw samples were used for P 106 determination followed by developing blue colour of phosphomolybdate complex using SnCl₂. The 107 absorbance was measured at 660 nm wave length in spectrophotometer and available P was 108 calculated with the help of a standard curve [10]. In case of K determination, 5 ml digest for grain and 109 2 ml for straw were taken and diluted to 50 ml volume for getting the desired concentration because of 110 the absorbance of samples could be measured within the range of standard solutions. The 111 absorbances were finally measured by flamephotometer. The content of S in the digest was 112 determined by adding acid seed solution followed by forming turbidity using BaCl₂. The intensity was 113 measured by spectrophotometer at 420 nm wave length [11]. 114

115 2.5 Nutrient uptake

116

117 Nutrient uptake was calculated from the measured yield and nutrient contents (grain and straw), and 118 expressed by the formula stated below:

Nutrient uptake
$$(kg ha^{-1}) = \frac{\text{Yield } (kg ha^{-1}) \times \text{Nutrient content } (\%)}{100}$$

121 2.6 Nitrogen use efficiency

120 122

123 Nitrogen use efficiency (NUE) generally accounts for the quantity of N accumulated in the plant, 124 showing the N uptake efficiency and the quantity of N utilized in grain production or the N utilization 125 efficiency of the plant to applied N. The NUE components: apparent N recovery efficiency (ANRE), 126 physiological N use efficiency (PNUE), and agronomic N use efficiency (ANUE) were calculated with 127 the following expressions [12]:

128

 $\begin{array}{l} \mbox{Apparent N recovery efficiency (\%)} = \frac{(N_f - N_c) \times 100}{NA} \\ \mbox{Physiological N use efficiency (kg kg^{-1})} = \frac{G_f - G_c}{N_f - N_c} \end{array}$ 129 130 Agronomic N use efficiency $(kg kg^{-1}) = \frac{G_f - G_c}{NA}$

131 132

133 where, N_f and N_c refer to the total above ground plant dry matter-N content (kg ha⁻¹) in the fertilized 134 and control (nonfertilized) plots, G_f and G_c refer to grain yield (kg ha⁻¹) in the fertilized and control 135 plots, and NA is the amount of fertilizer-N in kg ha⁻¹ applied. 136

137 2.7 Statistical analyses 138

139 All the collected data were analyzed for ANOVA with the help of the computer package program 140 MSTAT. The differences among the treatment means were evaluated by the Duncan's New Multiple 141 Range Test (DMRT) as outlined by [13].

143

147

142 3. RESULTS AND DISCUSSION

144 3.1 Nutrient contents in grain and straw of BRRI Dhan 29

145 146 <u>3.1.1 Nitrogen(N)</u>

148 The N contents in rice grain and straw were significantly influenced by the application of organic and 149 inorganic sources of N over control, ranged from 0.74 to 1.10% in grain and 0.41 to 0.71% in straw 150 (Table 1). The highest N content (1.11%) in grain was observed in the treatment T₁ (application of 151 N_{150} through urea) which was statistically parallel to treatment T_5 and T_6 . The lowest (0.83%) grain N was noted in the treatment T_0 (control) where no N fertilizer was applied. So, use of inorganic 152 153 fertilizers increased the N content in the rice grain markedly. It was noticed that the influence of T_1 on 154 the straw N contents was statistically superior to the other treatments. An increasing tendency of N 155 contents both in grain and straw was noted from the treatments receiving incremental doses of urea N 156 along with cowdung amended N compared to sole cowdung treated plot. The effect of 80% urea N 157 along with 20% cowdung N was more pronounced in both grain and straw N contents than other 158 combinations. It was also conceivable that the N content was comparatively higher than that of straw. 159 Application of S fertilizer increased the N content in straw. A significant increase in N content in rice 160 grain and straw due to application of organic manure and fertilizers have also been reported by many 161 investigators [14,15]. 162

163 <u>3.1.2 Phosphorus(P)</u>164

165 The P contents in grain and straw of BRRI Dhan 29 were significantly varied by different treatments 166 under the study (Table 1). In case of grain, the maximum P content (0.25%) was recorded in the treatment T_6 and the minimum was found in the treatment T_0 (control). From the Table 1, it was clear 167 168 that the treatment T₆ was statistically different from only control treatment. The results pinpointed that 169 P supplied to all the treatments in same amounts but the increased amount of P content was found in 170 the T_6 than that of the T_1 treatment. This might be due to the utilization of cowdung N on positive governance on the P content in grain. On the other hand, straw P content was almost lower than grain 171 172 and varied from 0.12 to 0.21%. The highest P content (0.214%) was observed in the treatment T_6 and 173 was statistically similar to those measured in the treatments T1, T2, T3, T4 and T5 having the values 174 0.21, 0.16, 0.18, 0.19 and 0.20%, respectively. Application of organic N as cowdung either alone or in 175 association with decremental rates of the advocated inorganic N as urea caused pronounced effect in 176 increasing the straw P content. Increase in P contents both in rice grain and straw increased due to 177 application of cowdung, poultry manures and chemical fertilizers were reported by other researches 178 [16,17].

179 180 **3.1.3 Potassium(K)**

180 181

193

182 The contents of K in grain and straw were governed profoundly by the different treatments (Table 1). 183 The highest content of K in grain (0.31%) was obtained in the treatment T_5 , which was statistically similar to that observed in the treatment T_1 , T_4 and T_6 . The treatment T_0 (control) produced the lowest 184 185 (0.28%) grain K content, which was statistically dissimilar to all other treatments. The highest K 186 content (0.88%) in straw was obtained in the treatment T_1 which was statistically similar to all other 187 treatments except control. It was also observed that the K content in straw was higher than that of 188 grain in all the treatments. The incorporation of increased doses of cowdung amended organic N 189 combined with reduced doses of inorganic urea N showed better credibility in increasing K contents 190 both in grain and straw. K contents in rice grain increased considerably due to application of sulphur 191 fertilizer. [18] reported that K contents in grain and straw were increased due to beneficial effects from 192 combined application of organic and inorganic fertilizers.

194 3.1.4 Sulphur(S)

195 196 Results in the Table 1 indicated that S contents in both grain and straw were statistically insignificant 197 (p > 0.05) due to different treatments. The highest value of S contents in grain (0.07%) was obtained 198 from both T₁ and T₆ treatments while the lowest was noted in T₀ (control). All the treatments caused an 199 increasing effect of sulphur content of rice grain. In straw, S contents ranged from 0.03 to 0.05%. The 200 treatment T₀ (control) had the lowest value of S content (0.03%). It was also revealed that the S 201 contents in grain were higher than that of straw in all the treatments. The incorporation of organic N 205

207

209

combined with reduced doses of inorganic urea N showed better performance in increasing S
 contents both in grain and straw over the control. [19] reported that application of manures and
 fertilizers increased the sulphur content both in grain and straw of rice.

206 **3.2 Nutrient uptake by grain and straw of BRRI Dhan 29**

208 3.2.1 Nitrogen(N)

210 Significant effects on N uptake by BRRI Dhan 29 were found in rice grain and straw (Table 2). The N uptake by grain ranged from 21.87 to 64.40 kg ha⁻¹. The effect of T_1 treatment receiving 100% N from 211 212 urea on N uptake by grain was statistically superior to all other treatments but alliance with the 213 treatment T₆. From the Table 2, it was clear that the uptake of N by grain by using 80% N from urea 214 with 80% cowdung amended N exerted greater effect compared to cowdung N alone or other 215 combinations. Application of S increased the N uptake by grain considerably. A significant linear relationship was observed between grain yield and grain N uptake (Figure 1a). The N uptake in grain from different treatments ranged from 18.14 to 43.24 kg ha⁻¹. The uptake of N was found maximum 216 217 218 (43.24 kg ha⁻¹) in the T_1 treatment and was statistically superior to the rest treatments. It was noted 219 that N uptake by grain was higher than that of straw. The total N uptake varied distinctly and ranged 220 from 40.10 to 107.60 kg ha⁻¹. The highest total N uptake (107.60 kg ha⁻¹) was found in the treatment 221 T_1 , which was statistically similar to T_6 treatment with total N uptakes of 103.82 kg ha⁻¹. The lowest 222 total N uptake (40.10 kg ha⁻¹) was manifested in the treatment T_0 (control) that was statistically inferior 223 to all other treatments and followed by the T₂ treatment. The total N uptake for the treatments ranked 224 in the order of $T_1 > T_6 > T_5 > T_4 > T_3 > T_2 > T_0$. [17] and [20] reported that application of N from 225 manures and fertilizers significantly increased the N uptake both in grain and straw of rice. 226

227 3.2.2 Phosphorus(P)

228 229 There was a significant variation in P uptakes by rice grain and straw due to different treatments. P 230 uptake ranged from 4.32 to 14.85 kg ha⁻¹ in grain and 5.21 to 12.99 kg ha⁻¹ in straw. The highest 231 uptake in rice grain was found in the treatment T_1 and was significantly similar to T_6 with the value of 232 12.80 kg ha⁻¹. The lowest uptake of P was noted in the control (T_0). From the Figure 1b, it was 233 observed that grain yield was significantly linked with grain P uptake. The highest P accumulation by 234 straw (12.99 kg ha⁻¹) was manifested in the treatment T_1 whereas the lowest (5.21 kg ha⁻¹) was 235 recorded in the treatment T_0 . The treatment T_1 was closely succeeded by the treatments T_4 , T_5 and T₆. However, all the treatments significantly increased the P uptake over control (T₀). The total uptake 236 was also different due to different treatments (9.52 kg ha⁻¹ in T_0 and 27.84 kg ha⁻¹ in T_1 (Table 2). The 237 238 treatment T₁ was statistically different from all other treatments on total P uptake but followed by those 239 recorded in the treatments T_5 and T_6 . The application of incremental doses of inorganic N performed 240 better in increasing P uptake compared to organic source alone. Similar result was also experienced 241 by other studies [14, 16, 17]. 242

243 3.2.3 Potassium(K)

244 The K uptake ranged from 8.54 to 17.84 kg ha⁻¹ in grain and 30.26 to 53.53 kg ha⁻¹ in straw (Table 3). 245 The highest uptake by grain (17.84 kg ha⁻¹) was found in the treatment T₁, which was statistically 246 247 dissimilar with the treatments T_4 , T_5 and T_6 that gave 12.23, 12.90 and 14.87 kg ha⁻¹ K, respectively. 248 Nonetheless, it was worthwhile to mention that the grain yield was significantly correlated with grain K 249 uptake (Figure 1c). In case of straw, the highest value (53.53 kg ha⁻¹) was appeared in the treatment T_1 and succeeded by that observed in the treatments T_4 , T_5 and T_6 . However, all the treatments 250 251 significantly enhanced the uptake over control (T_0). The total uptake was also shaped significantly due to different treatments and ranged from 38.81 to 71.36 kg ha⁻¹ (Table 3). The treatment T_1 had the 252 highest total uptake of K (71.36 kg ha⁻¹) which was statistically identical to T_4 , T_5 and T_6 treatments. 253 The least total uptake (38.81 kg ha⁻¹) was noted in the treatment T₀ (control). It was obvious that K 254 255 uptake by grain was much less than that of straw and the results were in agreement with [21].

257 3.2.4 Sulphur(S)

256

Table 3 showed significant effects on S uptake in rice grain and straw as well as in total uptake. All the applied treatments significantly influenced on S uptake by grain over the control treatment (T_0) but the effect of T_1 treatment on S uptake by grain was statistically superior and different from all other 262 treatments. A linear relationship between grain yield and grain S uptake was observed and presented 263 in the Figure 1d. The S uptake in straw from different treatments ranged from 0.86 to 1.68 kg ha⁻¹ and found maximum (43.24 kg ha⁻¹) in the T₁ treatment that was statistically parallel to T₄, T₅ and T₆ 264 265 treatments. It was noted that S uptake by grain was higher than that of straw. The highest total S 266 uptake (25.63 kg ha⁻¹) was noted in T₁ treatment, which was statistically different from all other 267 treatments and followed by T₆ treatment with the value of 20.96 kg ha⁻¹. The lowest total S uptake 268 (9.57 kg ha⁻¹) was observed in the treatment T_0 that was statistically inferior to all other treatments. 269 Similar findings were also reported by many researchers [20,22]. 270

271 3.3 Nitrogen use efficiency(NUE) of BRRI Dhan 29

272

273 The response of the N use efficiency (NUE) components due to organic and inorganic sources of N 274 varied and presented in Figure 2. The apparent N recovery efficiency (ANRE) by BRRI Dhan 29 275 ranged from 8.33% to 45.06% (Figure 2a). The data clearly indicated that the maximum apparent N 276 recovery (45.06%) was obtained with the 100% recommended doses of N from urea (T₁). However, similar results of ANUE (42.54%) was also found in T₆. The reasons for high recovery of applied N 277 278 could be the split application of urea in rice field that resulted in continuous supply of readily available 279 N from urea throughout the growth period of rice. It was also found that lower rates of urea N with 280 higher rates of cowdung amended N were not useful for the N recovery but the incremental rates of 281 inorganic N with lower rates of organic N improve the recovery of N. Similar observation was also 282 reported in other literatures [23,24]. On the contrary, the physiological N use efficiency (PNUE) varied from 2.40 to 43.55 kg kg⁻¹ (Figure 2b). The peaked value in respect of PNUE was noted in the treatment T_6 (43.55 kg kg⁻¹) followed by the treatment T_1 with the value of 43.50 kg kg⁻¹. Agronomic N 283 284 285 use efficiency (ANUE) is a term used to represent the response of rice plant in terms of grain yield to 286 N fertilizer. The range of ANUE varied from 0.20 to 19.60 kg kg⁻¹ with highest value in T₁ treatment 287 and lowest in T₂. This result suggested that application of recommended doses of N through inorganic 288 sources leading to efficient uptake and utilization of applied N. It was also clear that the sole 289 application of N through organic sources had the lowest ANUE. However, the ANUE increased when 290 reduced doses of organic N sources were applied along with incremental doses of inorganic N from 291 urea. These results were also in agreement with the other researchers [17,25].

320

321 4. CONCLUSION322

The present study was conducted to investigate the effects of different ratios of N supplied either from cowdung and/or urea or from their combinations on the changes in nutrient contents, uptake and use efficiency by BRRI Dhan 29. The results indicated that nutrient contents and uptake by the grain and straw of the crops ranked top when applied with sole application of inorganic N (urea), followed by the application of N in mixture (80% N from urea + 20% N from cowdung), while no nitrogen application (control) ranked in the bottom. The performance of 40, 60, 80, 100% manure amended N level
showed a relatively little comparable effect on nutrient contents and corresponding uptake. However,
there was an obvious contribution of N supplied from cowdung on N use efficiency components,
though the application of recommended dose of inorganic N from urea performed better in this case.
Further research should be focused on multiple locations with different paddy soils and climate to
scale up the optimum requirement.
