

Editor's Comments :-

1. There are some mistakes in references.
2. The abstract is not structured (as per author guidelines)
3. In Methods there are many missing subheadings (sample size, variables, study design, etc)

In the manuscript are the comments.

I think that manuscript need more review from authors.

Author's Feedback :- We complied these joint (Editorial and Reviewers) comments as a strategy towards serving time on reviewing procedure,

item	Reviewer Comments	Author's Feedback
1	I cannot find the evaluation. Only I find description	The term EVALUATION fits completely well in the article title. In scaling and metrics sciences, use of term is governed by the level of manipulation of data in the following progressive stages; Measurement, Assessment, Analysis and Evaluation. As presented, the use of data in this study had transited all the stages even to deductive evaluation, resulting in judgements. Assessing this article as "description" in technical sense suggests that work was only at first stage of qualitative research considered as narration of event that occurred.
2	Unstructured abstract. See author guidelines	
3	The common style in this case is [3-7]	It is done as highlighted in green colour
4	In the last part of instruction should be the objective of the study	It was already stated as highlighted in green colour
5	Study design, sample size, analysis. I cannot find the validity and repeatability of the questionnaire I cannot find any about statistical analysis and I cannot find any about approval of bioethics committee.	Study design: I have now stated. It was obvious that the study was not experimental nor quasi, therefore it was quite unnecessary to be wordy at this point since sampling procedure was quite detailed. Sample size: it was already stated as highlighted green Validity and Reliability: the scale were adapted from earlier validated scale with Cronbach alpha coefficient index of 0.662 Statistical tools adopted; examples had been specified. Bioethics: this study was population based and thus require only the verbal consent evident by their willingness to complete the questionnaire.
6	What are the basis for this affirmation?	It was needed to estimate the probable weight of the study outcome for deductive evaluation of proposed construct variables.
7	Please review all references	All are done.
