7
8 **Abstract**

9
10 **Background and Objective:**This paper aims at analyzing the effect of the inflammatory
11 periodontal disease condition on the peripheral nerve regeneration. **Methods:**We used 32 male
12 rats, divided in 4 groups: control (CG); periodontal disease (PDG); nerve injury (IG); periodontal
13 disease with nerve injury (IPDG). On the first experiment, the animals were submitted to a
14 bilateral ligature around the lower first molars. Then, on the fifteenth day, they were submitted to a
15 peripheral nerve injury and euthanized on the thirtieth day, then, their sciatic nerve and their right
16 hemimandibles were collected. **Results:**The induction of the periodontal disease was proved by
17 the histomorphometric of the mandible. When it comes to the nerve morphometric analysis, there
18 was no difference among the nerve fibers groups (NF) compared to the viable FN longer than 4
19 micrometers (μm), CG and PDG presented higher quantity of IG and IPDG, on the less than 4 μm
20 fibers, being similar in these groups. CG and PDG presented smaller quantity of nonviable fibers.
21 The NF diameter, axon and myelin sheath, CG and PDG presented diameters longer than 4 μm ,
22 while only the MS presented shorter than 4 μm difference, CG presented a longer diameter than IG
23 and IPDG. All groups depicted similar quantities of blood vessels, conjunctive tissue and cell
24 nuclei density, CG and PDG presented lower values than the other groups. **Conclusion:**We can,

25 therefore, suggest that induced periodontal disease did not influence the sciatic nerve process of
26 regeneration.

27 **Keywords:** Periodontitis, Inflammation, Sciatic Nerve, Nerve Crush, Nerve Regeneration.

28 **Introduction**

29 The periodontal disease (PD) is responsible for destroying the supportive tissue of the
30 teeth, as it stimulates an unbalance condition on the buccal region, promoting the growth of
31 bacteria and bacterial plaque as well as triggering local and systemic inflammation¹.

32 This systemic inflammation is originated by pro-inflammatory cytokines released at the
33 periodontal infection spot, which infiltrates on the blood system and reach other places, being, that
34 way, related to the increase of systemic changes, such as cardiovascular diseases, cerebrovascular,
35 atherosclerosis and Alzheimer's disease^{2,3}. The action mechanisms, though, are still not yet
36 clarified⁴.

37 Another known inflammatory condition is the peripheral nerve injury (PNI), which is
38 common and can decrease the patient's life quality, resulting in impairments in the long-term.
39 When the injuries cause damages only on the axons and their myelin sheath, they are characterized
40 as a second level injury, axonotmesis type, without any damage to the epineurium, being
41 mechanical traumas the most common cause⁵⁻⁷.

42 After the injury, a series of molecular and cellular change occur in the nerve,
43 characterizing the Wallerian degeneration, in which the axon and the myelin sheath (MS) suffers
44 degeneration⁸, leading to a macrophagic influx and Schwann cells proliferation, responsible for the
45 removal of these structures, creating a local inflammatory response due to the increase of pro-
46 inflammatory cytokines expression, as a factor of alpha tumor necrosis (TNF- α), interleukin 1 β
47 (IL1 β) and (IL6)^{9,10}.

48 When this stage is accomplished, the Schwann cells align themselves forming a band of
49 Bungners¹¹, mainly source of neurotrophic factors, relevant to the axon regeneration⁷, however, the
50 complete recovery is not very common, as it can be misdirected or associated with neuropathic
51 debilitating pain, often triggering a responsive inflammatory chronic reaction in this tissue¹².

52 Gurav² proposed a possible PD association with the nerve injury, in which the PD
53 through a systemic inflammation, would be responsible for the exacerbation of the neuro
54 degeneration, serving as a source of pro-inflammatory systemic factors, capable of effecting the
55 vascular integrity of the brain and which could perpetuate the chronic inflammatory process by the
56 activation of an innate immune response. Although the mechanism between the relation between
57 the PD and the decrease of the cognitive Alzheimer's disease is not clear yet, there is increased
58 evidences to support the role of the systemic disease evolution.

59 This way, this study aimed at analyzing the effect of the inflammatory condition of the
60 periodontal disease upon the experimentally induced peripheral nerve regeneration.

61

62 **Material and methods**

63 The research was carried at the Injury and Physical Therapy Resources Study Laboratory
64 (LELRF) in partnership with the Structural and Functional Biology Laboratory of the Western
65 State University of Parana (UNIOESTE). All experimental procedures were submitted and
66 approved by the Ethical Committee of Animal Use of UNIOESTE.

67

68 ***Sample Group***

69 We used 32 male *Wistarrats*, 8 weeks old, weighting an average 250g, from the
70 UNIOESTE central vivarium. The animals remained at the sectorial vivarium of LELRF, under
71 controlled conditions of temperature ($23 \pm 2^\circ$ C) and light (cycle of light-dark-of 12 hours), they
72 received water and commercial rat food at all times. The animals were distributed randomly in 4
73 groups of 8 animals in each:

- 74 • Control Group (CG), did not suffer intervention;
- 75 • Periodontal Disease Group (PDG), submitted to the induction of PD procedure by ligature
76 on the first day of the experiment;
- 77 • Nerve Injury Group (IG), submitted to a nerve injury after the fifteenth day of the
78 experiment;

- 79 • Periodontal Disease with Nerve Injury Group (IPDG), submitted to a PD induction by
80 ligature and nerve injury;

81 All animals were euthanized after the thirtieth day of the experiment.

82

83 ***Induction of Periodontal Disease Protocol / Experimental Periodontitis***

84 On the experiment's first day, the animals of the group DG and PDG weighted and
85 anesthetized with ketamine (100 mg/Kg), xylazine (50 mg/Kg) (Sespo IndustryandTrade Ltda, São
86 Paulo, Brazil), by *via* intraperitoneal, placed on the appropriate operatory table, which allowed
87 easier access upon the teeth on the posterior jaw region. With the support of a modified pinch and
88 an explorer probe, cotton ligatures number 40 were placed around the lower right and left first
89 molar. This ligature acted irritating the gingival margin for 30 days, provoking the accumulation of
90 bacterial plaque and, consequently, the development of the periodontal disease¹³.

91

92 ***Compression injury of the sciatic nerve experimental model***

93 On the experiment's 15th day, previous to the surgery procedure of compression injury
94 of the sciatic nerve, the IG and IPDG group were weighted and anesthetized. A trichotomy was
95 carried on the posterior region of the left thigh and, after, with the support of scalpel, and incision
96 parallel to the fibers of the biceps femoral muscle was done to expose the sciatic nerve and,
97 consequently, its compression with a hemostatic pinch, for 30 seconds. The pressure of the pinch
98 was the same in all animals, having as a reference the second rack's teeth, all of them done by the
99 same person, with anepineural suture placed as a mark in the injured spot^{14,15}.

100

101 ***Animal euthanasia***

102 On the experiment's last day (30th), all animals were weighted and anesthetized, a
103 dissection done, followed by the removal of 2 cm of the sciatic nerve, distal to the compression
104 procedures, for a morphological nerve tissue analysis. Soon after, the animals were euthanized by
105 guillotine decapitation and their left hemimandibles collected for posterior radiographic analysis.

106

107 ***Mandible histomorphometric analysis***

108 After the animals' euthanasia, the right hemimandibles side were collected, dissected and
109 fixed in a solution of 10% formaldehyde, for 24 hours. After this period, distilled water was used
110 to wash them and trichloroacetic acid (TCA) of 5% was used to decalcify for about 14 days. The
111 samples were dehydrated for 1 hour and half in alcohol 70%, 80%, and 90% and overnight alcohol
112 95%. Next day, they were put on alcohol 100% in 4 baths of an hour each.

113 After that, the material was diaphanized, impregnated and included in paraffin. Later on,
114 microtomy was done, with 7µm cuts in a microtome (*Hestion*®, *ERM3000*, *DaintreeScientific*, St.
115 Helens, Australia) and the slides colored with hematoxylin and eosin.

116 The measurement of the alveolar bone crest was done through a microscope attached to a
117 computer, which permitted capture images, through the *software LazEz*®. A measurement of the
118 shorter distance between the top of the buccal alveolar crest and the cementum-enamel junction
119 was done using an analyzing program of images *Image Pro-plus* 6.0 software. The measurements
120 were repeated once a day, in three different days, and then an average of the values was done¹⁶.

121

122 ***Sciatic nerve histomorphometric analysis***

123 The first fragment collected near the nerve injury was put in paraformaldehyde 7% in
124 PBS (pH 7,4), for 24 hours and, then, placed in glycine and after fixed in osmium tetroxide 2% in
125 PBS, dehydrated, diaphanized, infiltrated and put in blocks of histological paraffin to obtain the
126 transverse cuts of the nerve with a thickness of 5 µm¹⁷. Later on, the histological slides were
127 assembled, with 100x objective microphotography (4 fields), and analyzed through the *Image Pro-*
128 *plus* 6.0 software.

129 The collected images were analyzed according to following parameters: total number of
130 nerve fibers, total number of viable fibers and total number of nonviable fibers (the ones that did
131 not present definite layout permitting measurement) axon diameter, nerve fiber diameter and
132 myelin sheath thickness (given by the axon diameter minus the nerve fiber, divided by 2).

133 Aiming at distinguishing the nerve fibers with longer or shorter diameters, we used as a
134 basis Mazzer et al.¹⁸ and Livnat et al.¹⁹ studies, which described the distinction of the longer and
135 shorter fibers injury on the sciatic nerve, the reference of measure being 4 μm for an analysis of
136 the nerve fiber, higher or equal to 4 μm were considered longer diameter and fibers with less than 4
137 μm . Four pictures of each cut were taken, regarding of each part of the image, right and left
138 superior quadrant, right and left inferior quadrant, on the 100x objective. The analysis was done in
139 a blind way when it comes to the groups, 25 fibers of higher diameters were measured and 25 of
140 lower diameter per quadrant, totalizing 200 fibers per nerve, or even in its totality, when it did not
141 reach the number of fibers.

142 The second distal nerve injury fragment was fixed in paraformaldehyde 7% for 24 hours,
143 following the histological routine procedure for the inclusion in histological paraffin and then cut
144 transversally with 5 μm thickness. After that, colored with hematoxylin and eosin and
145 microphotographed in four fields, with the 100x objective, aiming at counting the cell nuclei and
146 blood vessels in the *Image Pro-plus 6.0* software. The exclusion borders were included in the
147 numbers, the analyzed object that touched the superior left borders, while the exclusion border was
148 the right inferior one. The conjunctive tissue was quantified through Masson Trichrome coloring
149 through counting the pixels using a rule of three, given by the quantity of conjunctive tissue
150 divided by the quantity of pixels in the image, in the *Image Pro-plus 6.0*.

151

152 ***Data Analysis***

153 The results were expressed and analyzed through a descriptive and inferential
154 statistics analysis. Firstly, they were evaluated by its normality according to the Shapiro-Wilk test
155 and, as they presented normal distribution, the Anova unidirectional test was used, followed by the
156 Tukey test when there was a significant difference. The variable numbers were analyzed through
157 the BioEstat 5.0 test. We considered it significant when $p < 0.05$.

158

159

160 **Results**

161

162 ***Measuring the distance between the alveolar bone crest to the lower first molar cementum-***
163 ***enamel junction***

164 By the measurement of the distance between the alveolar bone crest to the lower first
165 molar cementum-enamel junction, we could verify that there was a loss of supportive tissue from
166 the animals exposed to the experimental periodontal disease ($p < 0,05$), showing effectivity
167 regarding the induction of the periodontal disease on the alveolar bone tissue (Table 1).

168

169 **Table 1** - Measuring the distance between the alveolar bone crest until the lower first molar
170 cementum-enamel junction.

Group	Average
CG	17.18 ± 3.47 A
PDG	34.38 ± 9.73 B
IG	17.08 ± 3.56 A
IPDG	34.59 ± 9.68 B

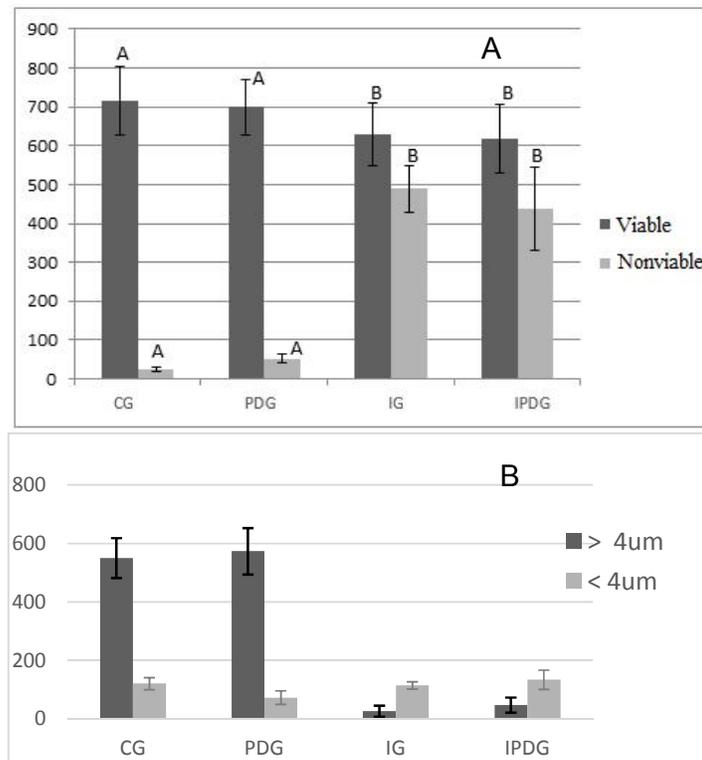

171 CG, control group; PDG, periodontal disease group; IG, nerve injury group; IPDG, periodontal
172 disease group with nerve injury. Different letters indicate significant statistic difference. Values
173 represent an average ± standard deviation.

174

175 ***Nerve fibers total, viable and nonviable nerve fibers***

176 In regards of total number of nerve fibers, there was no statistic significant difference
177 among the groups ($p = 0,625$). For the quantity of nonviable nerve fibers of the CG and PDG
178 groups, they present similar behaviors, when it comes to the groups that had a peripheric nerve
179 injury, IG and IPDG, they showed an increase on the number of nonviable fibers ($p < 0,05$), (Image
180 1A). The total number of longer than 4 μm viable nerve fibers, the CG and PDG presented similar
181 results, the groups that had the peripheric nerve injury showed a decrease on the total number of
182 viable fibers ($p < 0,05$). For fibers shorter than 4 μm , the PDG presented the lowest quantity number
183 of viable fibers than the CG and IPDG ($p < 0,05$), (Image 1B).

184

185

186 **Image 1 - A-** Nerve fibers total viable and nonviable. **B-** Nerve fibers total viable, fibers total
 187 longer and shorter than 4 micrometers. CG, control group; PDG, periodontal disease group; IG,
 188 nerve injury group; IPDG, periodontal disease group with nerve injury. Different letters indicate
 189 significant statistic difference. Values represent an means ± standard deviation.

190

191 ***Nerve fibers diameter***

192 On the analysis of the longer than 4 µm nerve fibers diameter, CG and PDG presented
 193 similar results, while the other groups that had the peripheric nerve injury showing a decrease on
 194 the fiber never diameter (p<0,05). For shorter than 4 µm fibers, there was no difference among the
 195 groups (p=0.219) (Table 2).

196 **Table 2 - Nerve fibers diameter, longer and shorter than 4 micrometers.**

Group	> 4 µm	< 4 µm
CG	86.95 ± 0.68 A	29.44 ± 0.17 A
PDG	88.65 ± 0.70 A	29.18 ± 0.25 A
IG	44.77 ± 0.09 B	30.86 ± 0.11 A
IPDG	45.20 ± 0.23 B	30.62 ± 0.30 A

197 CG, control group; PDG, periodontal disease group; IG, nerve injury group; IPDG, periodontal
 198 disease group with nerve injury, μm – micrometers, > - longer, < - shorter. Different letters
 199 indicate significant statistic difference. Values represent an average \pm standard deviation.

200

201 *Axon diameter*

202 Regarding the axon shorter than 4 μm diameter fiber diameter, CG and PDG presented
 203 equivalent results, while the groups that had peripheric nerve injury showed a decrease on the axon
 204 diameter ($p < 0,05$). For shorter than 4 μm fibers, the CG presented a shorter value than the other
 205 groups ($p < 0,05$), (Table 3).

206

207 *Myelin Sheath Thickness*

208 For longer than 4 μm fibers, the CG and PDG presented similar results, the other groups
 209 who had the peripheric nerve injury showed a decrease on the number of myelin sheath thickness
 210 ($p < 0,05$). While the other shorter than 4 μm fibers, CG presented a higher number of thickness
 211 than the groups with peripheric nerve injury ($p < 0,05$), (Table 3).

212 **Table 3** -Axon diameter, longer and shorter than 4 micrometers. Myelin Sheath Thickness of
 213 fibers longer and shorter than 4 micrometers.

Group	Axon		Myelin Sheath Thickness	
	> 4 μm	< 4 μm	> 4 μm	< 4 μm
CG	42.23 \pm 0.18 A	14.08 \pm 0.16 A	1.60 \pm 0.54 A	0.77 \pm 0.06 A
PDG	45.46 \pm 0.26 A	17.25 \pm 0.12 B	1.80 \pm 0.44 A	0.67 \pm 0.04 AB
IG	26.07 \pm 0.20 B	18.28 \pm 0.12 B	0.93 \pm 0.06 B	0.62 \pm 0.02 B
IPDG	26.66 \pm 0.23 B	19.14 \pm 0.14 B	0.92 \pm 0.10 B	0.65 \pm 0.06 B

214 CG, control group; PDG, periodontal disease group; IG, nerve injury group; IPDG, periodontal
 215 disease group with nerve injury, μm – micrometers, > - longer, < - shorter. Different letters
 216 indicate significant statistic difference. Values represent an average \pm standard deviation.

217 ***Quantifying the blood vessels, cell nuclei and conjunctive tissue percentage***

218 There was no significant statistic difference on the blood cells analysis among the groups
 219 ($p=0,41$). Regarding the cell nuclei, CG and PDG presented similar behaviors; the groups
 220 submitted to the peripheric nerve injury presented higher cell nuclei cell density ($p<0,05$). Besides
 221 that, the IPDG presented a smaller value in relation to the IG ($p<0,05$). The results of the
 222 conjunctive tissue were equivalent for the CG and PDG, the groups submitted to the peripheric
 223 nerve injury presented a higher conjunctive tissue percentage ($p<0,05$), (Table 4).

224

225 **Table 4** – Quantifying the blood vessels, cell nuclei and conjunctive tissue percentage.

Group	Blood vessels (n)	Cell nuclei (n)	Conjunctive tissue (%)
CG	14.0 ± 5.33 A	115.6 ± 20.9 A	2.38 ± 0.27 A
PDG	9.4 ± 0.89 A	109.8 ± 15.1 A	2.22 ± 0.25 A
IG	15.0 ± 4.35 A	431.6 ± 88.9 B	3.25 ± 0.21 B
IPDG	15.8 ± 10.63 A	319.4 ± 75.0 C	3.54 ± 0.45 B

226 CG, control group; PDG, periodontal disease group; IG, nerve injury group; IPDG, periodontal
 227 disease group with nerve injury. Different letters indicate significant statistic difference. Values
 228 represent an average ± standard deviation.

229

230 **Discussion**

231 Up until this moment, we could not find studies that would associate PNI with PD, this
 232 way our research aimed at evaluating the effects of these two conditions associations, once the PD
 233 is a disease of inflammatory characteristics. Other studies, however, have increasingly related the
 234 PD as a risk factor for the development of systemic diseases, through the inflammation of its
 235 pathogenic agents would result in reaching the blood circulation of the affected individuals^{4,20,21}.

236 The sciatic nerve is formed of long nerve fibers, which originates from the lumbosacral
 237 plexus responsible for the motor and sensory characteristic of the lower limbs innervation. Due to
 238 its long extension, traumas and ischemia, it can cause relatively common damages, causing inferior
 239 members disfunctions⁷. This way, the study of the peripheral nerve injury, several authors chosen
 240 for experimental compression injury models, classified by Seddon²² an axonotmesis, that involves

241 direct damages to the axon besides the focal de-myelinization, preserving the supporting structures
242 and maintaining the epineurium continuity, which has the function of guiding the new axon to the
243 regeneration of the target-organ²³.

244 In this current study, conducted for 37 days, 15 days after the experimental axonotmesis,
245 it was possible to observe that all the groups presented a similar average in relation to the total
246 number of fibers present in the sciatic, differing only in the number of viable and nonviable fibers,
247 that being the CG and PDG presented a higher number of viable fibers, while the nonviable fiber
248 values were lower compared to the IG and IPDG (Image 1A and 1B), these presented a higher
249 number of nonviable fibers pointing at the studies of Antunes et al.¹⁴ when depicting that the PNI
250 was responsible for structural changes in these nerve fibers.

251 There was no reduction on the total nerve fibers in those injured groups, however, the
252 nerve structures were shorter and thinner than the others, that means, in the IG and IPDG there was
253 a significant increase on number of fibers shorter than 4 μm (Table 2), showing a possible nerve
254 regeneration, supporting the studies of Sta et al.²⁴, which pointed at the recent regenerated axon
255 presented a smaller diameter than the survival axon and yet not myelinated, explaining, then, the
256 higher number of viable fibers in shorter than 4 μm diameters in these groups.

257 According to Svehlisen and Dahlin²⁵, deficiencies (MMP) 9 and 2 in special, harmed
258 the re-myelinization interfering in the intranodal length and the regenerations of the Ranvier nodes,
259 which could be suppressed by the systematic effects provoked by the established periodontal
260 disease, which could cause an increase on the release of MMPs, after the inflammatory stimulus,
261 among other actions taken to a destruction of local tissue that supports the teeth²⁶. Still in
262 accordance with Toregeani et al.²⁶, the PD increases the release and the production of pro-
263 inflammatory factors as the prostaglandins, MMPs, IL 1 beta, IL6, TNF alfa and C-reactive protein
264 and it decreases the IL10 and IL4 which are anti-inflammatory cytokines²⁷, those act on the nerve
265 regeneration, which means that the most elevated levels of circulating inflammatory biomarkers
266 could play a role on the systemic disease contribution⁴. Our study, however, could not have been
267 carried out without this action once that even on the IPDG group presenting low numbers of viable

268 fibers and more quantity of viable fibers in comparison with the IG, there was no statistic
269 significant difference between them, those inflammatory characteristics, therefore, systematically
270 triggered by the PD did not present sufficient factors to positively interfere, but, on the other hand,
271 they also did not play any negative role on the nerve regeneration.

272 The local inflammation on the PNI, consequently, is responsible for a series of
273 histopathological events associated with morphological and functional changes, triggering the
274 nerve degeneration and, soon after, the cleansing of myelinic and axon detritus, contributing for an
275 environment of regeneration⁸, besides, this also results in the reorganization and proliferation of
276 Schwann cells, responsible for the neurotrophic factors of the axon growth¹⁰. This way, the
277 systemic inflammation could be a factor to aggravate the local inflammation turning it into a
278 dysfunction and increase on the local inflammatory process, making the nerve fiber degeneration
279 worse, even though this change was not observed in our study.

280 When it comes to the diameter of the nerve fiber, the axon and the myelin sheath, longer
281 than 4 μm fibers, the CG and PDG presented better results than the groups that were submitted to
282 the PNI, highlighting that at the changes that may occur in their structures due to the PNI, where a
283 decrease on these three structures occurs, also stated at the Antunes et al.¹⁴ studies, in which they
284 observed their presence on thinner structures, indicating that it would be take a longer study time
285 to register the significant data related to these structures' diameter.

286 On shorter than 4 μm fibers, there was no statistic significant difference on the nerve
287 fiber's diameter, while the axon diameter and the CG presented a shorter average than the others,
288 pointing at an increase of these axons on groups submitted to PNI, which could be justified by the
289 nerve regeneration that is taking place on these groups. Although the IPDG was not significant, it
290 presented a thicker MS than the IG, which could suggest the hypothesis that the PD could have
291 played a sensitizing effect on the MS regeneration, probably due to the release of MMP effect in
292 systemic level, acting on the regeneration of this structure²⁵.

293 When we compared the CG and the PDG with the groups submitted to the nerve injury, it
294 was possible to observe the lower values of MS, showing that the re-myelination was not yet

295 totally present in these groups, result also found on the Sta et al.²⁴ study, where they analyzed the
296 electrophysiologic, behavior and morphologic parameters relation to the sciatic nerve in rats after
297 the compression injury. They observed that the first signs of myelinization started after the 21st
298 post-surgery day, highlighting that it would possibly require a longer time to study, register
299 significant data, as this study could only be carried out up until the 15th peripheral nerve injury
300 post-surgery day, not being possible to observe the complete de-re-myelinization signs.

301 Analyzing the blood vessels, we did not find statistic differences among the groups, it is
302 known, however, that, after the nerve injury, angiogenesis occurs²⁸. Relevant aspect, this fact
303 points at the vessels injuries after the nerve injury, forming an endoneurial hematoma, and
304 consequently ischemia, which can harm the nerve regeneration due to the lack of nutrients and
305 support for the removal of the myelin and what was left of the axons²⁹. It could have been, this
306 way, in our study, a factor to harm the nerve regeneration as we did not observe an increase on the
307 blood vessels quantity after the LNP.

308 When it comes to the cells nuclei analysis and the conjunctive tissue percentage, the IG
309 and IPDG showed higher values, that means, the PNI increases the number of the cell nuclei and
310 the conjunctive tissue percentage. During the process of regeneration, the nerve fibers need to be
311 restored quickly, before the bungner bands are closed, otherwise, a scar tissue occur in an
312 inaccessible new innervation area³⁰, which could have happened to the groups submitted to the
313 PNI, justifying the increase on the cells nuclei due to the fibroblasts presence, resulting on a high
314 number of endoneurial tissue. Apart from that, the inflammatory and Schawnn cells can be present,
315 as after 15 days after the injury, it is still on the regeneration phase, that could occur about 7 to 28
316 days after the injury²⁴, phase characterized by the increase of these cells which will align and be
317 responsible for the bungnersbands formation, resulting in an environment rich in trophic factors,
318 permitting an axonal regeneration and directing them to the distal stump⁶.

319 Proving the efficiency of the experimental PD model, the mandibles measurement made
320 it possible to observe the distance between the alveolar crest until the animals' lower first molar
321 cementum-enamel junction, showing the effectiveness of the technique to induct the periodontal

322 disease by ligature, resulting on the absorption of bone tissue. These findings are in accordance
323 with the Nassar et al.¹³, studies that put these characteristics as signs of DP occurrence.

324 According to Toregeani et al.²⁶, the development of PD, after the inflammatory stimulus,
325 an increase of the prostaglandins e2 and MMP occur, which leads to the extracellular gingival
326 destruction and of the periodontal ligature, stimulating the reabsorption of the alveolar bone. The
327 effect of the MMPs release and the bacterial proliferation are the activation of several cells such as
328 fibroblasts, keratinocytes, macrophages and endothelial cells, responsible for the bone reabsorption
329 through the element fragmentation of the extracellular osteoclasts matrix.

330 Therefore, up until it was possible to study, we can conclude that the experimentally
331 induced periodontal disease did not influence on the regeneration process of the nerve tissue after
332 the induction of a peripheric nerve injury.
