Assessment of clinical outcomes of outpatients following chest X-ray imaging performed at King Abdul–Aziz Medical City, Saudi Arabia, Riyadh

11

ABSTRACT

12

Background: Chest X-ray imaging is one of the most commonly performed daily routine investigations in many of the hospitals and diagnostic centers around the globe. Many people have chest X-rays before surgery, although a diagnosis is made based on the findings in only a few cases and each procedure adds to the radiation dose accumulation. According to the American college of Radiology (ACR), most CXR radiograph are less effective and should only be recommended based on the appropriateness criteria including elderly and high risk patients. Never theless the issue of replacing X-rays with other technique remains uncertain and mandates further investigation.

Aims: To assess and identify the clinical outcomes of outpatients following chest X-ray imaging performed.

Materials and Methods: In total, the data for 185 patients (83 men, 102 female; age range 15 to 90 and above) who underwent chest X-rays were analyzed. This is a retrospective quantitative study design and data was collected from medical records using stratified randomly sampling technique held at King Abdul–Aziz Medical City, Saudi Arabia, Riyadh in Radiology Department from September, 2017 to March, 2018

Results: Analysis of the collected data of a total of 185 patients revealed that 73.5% of the patients had negative radiological findings, while 26.5% had positive radiological findings. The majority of patients were females, comprising 55.1% of the total sample size, while 44.9% were male patients.

Conclusion: From the results of our study, we conclude that that most cases had negative radiological findings regardless of the gender. The daily routine chest radiograph can be avoided by replacing other imaging modalities.

18 1. INTRODUCTION

19

A simple way to detect pathology in the human body is by X-ray imaging. X-rays are electromagnetic waves that can pass through a patient's body quickly and X-ray imaging is relatively harmless because the dose is carefully monitored. Ionizing radiation related examinations are capable to cause a harmful effect to the human body thereby the alternate way of replacing X-rays with other technique to avoid the possibility of damage caused by Xrays still a justifiable issue. (1-2). Chest X-rays are one of the most commonly performed

examinations in many hospitals and diagnostic centers around the globe. (3) Previous 26 27 studies of the rate of X-ray examinations indicated that 48 million chest X-rays have been 28 performed over the years. Chest radiography is the most frequently done examination 29 among the intubated and mechanically ventilated patient. It is also performed both pre- and 30 post-operatively to identify abnormalities of the lungs and airways, heart and blood vessels 31 and bones. (4) On the other hand, the dose received by the patient that might lead to biological effects is a cause for concern. Many people had a chest X-rays before surgery, 32 33 although a diagnosis is made based on the findings in only a few cases and each procedure 34 adds to the radiation dose accumulation. Furthermore, some hospitals require every patient 35 to have a chest X-ray. For those patients who did not obtain a diagnosis from the X-ray, the 36 risk of radiation damage remains, even at low doses. (5) According to data collected for 37 2014, among 1,787 pre-operative chest X-rays performed in patients undergoing elective surgery, there was no official report for 827 of the films. Moreover, these data revealed that 38 39 cardiovascular disease referring to the most common pathologies (45.8%) identified by 40 chest X-rays, followed by systemic disease (17.7%) and healthy patients aged over 45 years 41 (16.8%) respectively. One study showed that chest X-rays did not affect the decision of 42 radiologists to refer patients for surgery. The Royal College of Radiologists published the 43 first major review of the pre-operative chest radiograph, which showed that this type of 44 imaging did not alter the decision made to undergo elective non-cardiopulmonary surgery in 45 10,619 operative or anesthetic patients. (6-10) The probability of abnormalities detected in 46 chest X-rays increases with the age of the patient. (11-13) One study showed that the chances of having chronic disorders, such as cardiomegaly and chronic obstructive 47 48 pulmonary disease, increased with ages. (14) A huge number of chest radiograph are done in medical centers across the Saudi Arabia annually mainly in the ICUs, these could cause a 49 heavy logistic and financial burden.(26) The overall aim of the study is to provide the 50 empirical evidence of the diagnostic chest X-ray imaging on the importance of diagnosing 51 52 different pathologies and their outcomes in clinical setting performed at King Abdulaziz 53 Medical City : and to what extent the policy in place could be modified in favor of using on 54 demand instead of current daily routine practice.

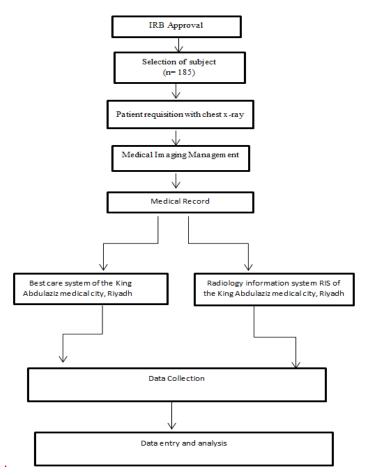

55

56 2. MATERIAL AND METHODS

57

58 This study was conducted at King Abdul-Aziz Medical City (KAMC), one of the largest 59 medical cities in Riyadh, which is under the administration of the Ministry of the National 60 Guard Health Affairs (NGHA). Referring to our study setting and subject, chest X-rays were performed in the Radiology Department of the Emergency and Ambulatory Care Units. All 61 62 chest X-rays were performed in male and female outpatients aged over 14 years. According 63 to the NGHA data, the number of subjects visiting the Emergency and Ambulatory Care Unit 64 of the Radiology Department for chest X-ray is estimated to be 3,096 per month with a 7% margin of error and 95% confidence level. The minimum sample size required was 185, 65 66 calculated using the Rao soft online sample size calculator. The Stratified Random Sampling 67 technique was used. The data for subjects who underwent chest X-rays during the period 68 from January to December were collected using a suitably structured form. The collected 69 data were entered into Microsoft Excel spreadsheets and transferred to SPSS version 22 for 70 statistical analysis. Descriptive statistics were used to explain the demographic 71 characteristics of the subjects according to availability of the records in the picture archiving 72 communicating system (PACS) of the Radiology Department. Frequencies and percentages 73 were also used to represent the information regarding the usefulness of pre-operative chest 74 X-rays, most common diseases affecting chest radiographs and the ratio between the abnormal and normal radiological finding of the subjects. Appropriate statistical tests were 75 76 used based on the types of variables and the data.

78 **Figure 1**: Outline of the study

79 80

81

82 3. RESULTS

83

Demographic characteristics: It is reported that overall 55.1% of 185 patients were female and 44.9% were male. The data for 185 patients who underwent chest X-rays were analyzed. All of the subjects were aged over 14 years and seen as outpatients at the Radiology Department of King Abdul–Aziz Medical City. Most of the patients were aged from 61 to 70 years (22.8%), followed by the group aged from 51 to 60 years (16.8%). By contrast, patients in the 15 to 20 years and 91 to 100 years age groups comprised only 6.5% and 2.2% of the study sample

91

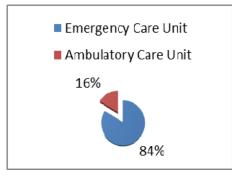

Table1.Demographic characteristics amongst the patient visiting King Abdul-Aziz
 Medical City (n=185), Riyadh, Saudi Arabia, 2017

Demographic Characteristics	Number & percentage

Gender Male Female	83 (44.9%) 102 (55.1%)
Age (y)	
15-20	12 (6.4%)
21-30	21 (11.4%)
31-40	20 (10.8%)
41-50	21 (11.4%)
51-60	31 (16.8%)
61-70	41 (22.8%)
71-80 y	22 (11.9%)
81-90 y	13 (7%)
91-100 y	4 (2.2%)

98 Sample according to variable of X-ray unit: Data were collected from 30 patients in the
 99 Ambulatory Care Unit and 155 in the Emergency Care Unit 155 patients, representing 16.2%
 100 and 83.8% of the total sample as shown in the Figure 1.

Fig.2. Distribution of the sample individuals according to the variable of X-rays Unit visiting King Abdul-Aziz Medical City (n=185), Riyadh, Saudi Arabia, 2017

Variable of chief complaint: As shown in the Table 2, the highest proportion with 30.3% of the sample individuals had chest pain, followed by shortness of breath 25.4%, routine cases by 13.5%, pre-operation cases, trauma & pre-employment, and abdominal pain were 4.3%, 3.8%, and 2.2% respectively. Similarly, atelectasis & pneumonia were 1.6% and Cough, Palpitations, Nasogastric tube, Fever, pneumothorax, Vital Signs, Lymphadenopathy and follow up cases were represented by 1.1% while Neck swelling, Upper abdominal pain, Hospital Admission, Cholangitis, Infection, Leg swelling, Dysphagia, Chronic obstruction pulmonary disease, Follow-up, Post-operation were 0.5% of the total population.

Table 2. Distribution of the sample according to the variable of complaint or indication

Chief complaints	Number & Percentage of subjects N=185						
	No.	%					
Chest pain	56	30.3					
Shortness of breath	47	25.4					
Routine	25	13.5					
Pre-operation	8	4.3					
Trauma	7	3.8					
Pre-employment	7	3.8					
Abdominal pain	4	2.2					
Atelectasis	3	1.6					
Pneumonia	3	1.6					
Cough	2	1.1					
Palpitations	2	1.1					
Nasogastric tube	2	1.1					
Fever	2	1.1					
Pneumothorax	2	1.1					
Vital Signs	2	1.1					
Lymphadenopathy	2	1.1					
Follow-up	2	1.1					
Neck swelling	1	0.5					
Upper abdominal pain	1	0.5					
Hospital Admission	1	0.5					
Cholangitis	1	0.5					

Infection	1	0.5
Leg swelling	1	0.5
Dysphagia	1	0.5
Chronic obstruction pulmonary disease	1	0.5
Post-operation	1	0.5

123

124

Radiological finding and their related diseases: It reported that in total, 136 (73.5%) of the patients had negative radiological findings which indicate that there were no clinical impression of any pathological finding on the radiograph as per the clinically-relevant reports from the PACS (picture archiving and communication system), while 49 (26.5%) had positive radiological findings. Furthermore, among the total number of patients (185), 135 (73%) had no related diseases, 40 (21.6%) had lung disease, six (3.2%) had heart disease and four (2.2%) had bone diseases

132

133Table 3. Distribution of the sample according to the variable of Results and their134related diseases

135

Variable	Number & percentage of subjects N=185
Results	
Positive	30 (16.1%)
Negative	155 (83.9%)
Related Diseases	
None	135 (73%)
Lungs	40 (21.6%)
Heart	6 (3.2%)
Bones	4 (2.2%)

136

137 Comorbidities: From the Table 4, it is clearly indicated that pleural effusion was the most 138 common pathology finding (8.1%), followed by enlarged cardiac silhouette in five patients 139 (2.7%), prominent bronchovascular markings and pulmonary edema each identified in four 140 patients (2.2%). Cardiomegaly, atelectasis, hyperinflation and infection were each identified 141 in three patients (1.6%). Two patients were affected by pneumonia (1.1%), while 142 pneumothorax, unknown lung disease, cancer, compression fracture, spinal degeneration 143 and left para-tracheal soft tissue density were each identified in one patient (0.5%).

144

145Table 4. Distribution of the sample according to the variable of comorbidities

	Number & Percentage of subjects N=185
Dedialogical Dathalogy	

_	No.	%
None	136	73.5%
Prominent bronchovascular markings	4	2.2%
Cardiac silhouette enlarged	5	2.7%
Pulmonary edema	4	2.2%
Infection	3	1.6%
Hyperinflation	3	1.6%
Pleural effusion	15	8.1%
Osteopenia	1	0.5%
Atelectasis	3	1.6%
Cardiomegaly	3	1.6%
Pneumothorax	1	0.5%
Lung Disease	1	0.5%
Cancer	1	0.5%
Compression fracture	1	0.5%
Spinal degenerative	1	0.5%
Left para-tracheal soft tissue density	1	0.5%
Pneumonia	2	1.1%

148 4. DISCUSSION

149

In this study, we analyzed data from 185 randomly selected patients in King Abdul-Aziz 150 151 Medical City, Riyadh. This study is first of its kind in Riyadh city to the best of our knowledge 152 and very few similar studies were available for comparison worldwide. Most of the studies 153 were found to be related to routine chest x-rays in intensive care units and critically ill 154 patients. Based on our study the data were collected from the Emergency Care Unit (83.9%) 155 and Ambulatory Care Unit (16.1%). Most of the patients were female 55.1%, whereas male patients were 44.9%. The main indication for chest X-ray was chest pain (56/185 patients; 156 157 30.3%), followed by shortness of breath, routine chest examinations, Pre-operation X-rays 158 pre-employment examination, trauma patients and patients with abdominal pain, atelectasis 159 and pneumonia. The eighth most common indications were palpitation (irregular rapid 160 heartbeat), cough, vital signs, fever, nasogastric tube, lymphadenopathy and pneumothorax. 161 The least frequent indications were neck swelling, upper abdominal pain, and admission, 162 cholangitis, infection, leg swelling, dysphagia, and pre-stent operation, post-operation, 163 follow-up and chronic obstructive pulmonary disease. According to the consensus opinion of 164 the American College of Radiology-expert panel realized that the daily-routine radiographs 165 are indicated for patients with acute cardiopulmonary problems and for patients receiving mechanical ventilation. (21) Furthermore in another study, consensus was reached that 166 CXRs should be considered routinely after certain procedures (for example, insertion of 167 168 feeding tube, endotracheal tube, central line catheter, and chest tube), (22) Our results also 169 indicate that (73.5%) of the patients were reported as no radiological impression or pathological finding on the radiograph as per the clinically-relevant reports form the PACS (picture archiving and communication system), with positive findings in only 26.5% of the patients. In relevant to previous study a total of 65 ICUs was received the questionnaire and it was reported that chest radiographs are considered essential for verification of the position of invasive devices (81%) and for diagnosing pneumothorax, pneumonia or acute respiratory distress syndrome (82%, 74% and 69%, respectively) There is notable lack of consensus on chest radiography practice in the Netherlands. (23)

In a study of the prevalence and characteristics of abnormal pre-operative chest X-rays 177 in 960 patients undergoing elective surgery. Dej-arkom et al.⁽⁷⁾ reported positive findings in 178 179 50.5% of the sample. It can be speculated that the high incidence of abnormalities identified 180 in chest radiographs was because some of the patients underwent cardiothoracic and 181 cardiac catheterization. In another study it was stated that radiological finding was the 182 decrease in abnormalities presumed to be present on CXRs. Indeed, a 30% reduction in 183 expected predefined findings was observed. (24) Furthermore, in another study, the safety of 184 abandoning routine CXRs in critically ill patients remains uncertain and mandates further 185 investigation. (25) In view of the fact to similar study, there is lack of consensus on chest 186 Radiography and the value and effectiveness of quality in daily routine chest radiography 187 may doubt. (23)

188 189

190 4. CONCLUSION

191

192 Our study revealed negative radiological findings in 73.5% of the chest X-rays performed at 193 the King Abdulaziz Medical City. Chest pain and shortness of breath were the most common 194 indications for chest X-rays in the majority of patients. Subsequently, the majority of the 195 radiological findings were related to lung disease, whereas bone disease was rare, with 196 pleural effusion as the most prevalent condition. Based on these findings, we suggest replacing X-ray imaging with other examinations, such as medical ultrasound, to minimize 197 the risk to patients of the effects of ionizing radiation. To conclude, similar studies with large 198 199 samples are required in order to get empirical evidence and it will definitely relieve to some 200 extent towards the financial burden and heavy logistic in the health care sector of Saudi 201 Arabia.
