

Potentials of Plant Oils in Pruritus Alleviation

ABSTRACT

Aims: To systemize and summarize the current understanding of the incorporation of plant oils in pruritus alleviation.

Methodology: Literature was searched using online databases such as MEDLINE/PubMed, Google Scholar and Science Direct with the following inclusion criteria: 1) conducted/written no sooner than 1991 and published as full articles in journals and books; 2) each article meets the specific characteristics of its according type of therapies.

Results: A total number of 51 articles was found and enlisted into 4 categories: moisturizers, antihistamine, neuromodulators and topical cannabinoid; each was directly examined and reviewed.

Conclusion: Plant oils have high potentials in the alleviation of pruritus, with those in the moisturizers category show the most positive successful outcomes.

Keywords: *itch, pruritus, alleviation, moisturizers, antihistamines, local anesthetics, phytocannabinoid.*

1. INTRODUCTION

Pruritus, or itch, is commonly defined as an “unpleasant sensation that elicits the desire or reflex to scratch” [1]. It usually is a symptom of various diseases and generates a wide spectrum of intensity, from mildly irritating to incapacitating. Prior to the past two decades, pruritus was not of research interest because scientists regarded it as a sub-group of pain, thus need not having any special treatments, according to the intensity theory [2]. However, as perceptions changed with new theories arose, research interest shifts and a number of studies on the treatment of itch were conducted. Yet, their efficacy has not been adequately proved, and there laid grounds for novel therapies. Among other alternatives such as topical antihistamine, corticosteroids, etc., plant oils have recently been in the highlight because of their natural origin as well as seemingly side-effect free properties. Nevertheless, evidences for such plant-based therapy are either little or uncategorized. This review aims to summarize the existing works in plant oils’ potentials to alleviate itch.

Plant oils are oils derived from plants by different methods such as distillation or solvent extraction. They can be extracted from various parts of the plants, such as root, stem, leaves, etc., thus yielding different constituents and properties. By that definition, the oils broadly fall into two categories – fixed and essential oils.

Fixed oils are customarily extracted from seeds or fruits of the plants and consist mostly of triglycerides, whose fatty acids such as linoleic or oleic acid are reported to have possible health effects. They usually appear dense and nonvolatile. Because of the high unsaturated to saturated fatty acids ratio, fixed oils remain liquid in room temperature or normal settings, thus making them a safe carrier for therapeutic drugs. Essential oils, on the other hand, are commonly extracted from flowers, leaves or the whole aerial part of the plant. They are responsible for the plants’ aromas and flavors with high volatility. Their secondary metabolites such as terpenoids, shikimates, polyketides and alkaloids are unique and thus served as central highlights for researchers in phytochemistry.

This article is structured based on B. Elmariah’s original review “Topical Therapies for Pruritus”[3] with several adjusted remarks. To be specific, the review shall not be covering all of the categories listed either because of their incompatibility to plant oils’ properties or the lack of reliable evidences. Moreover, the exact mechanism of each category shall not be discussed as they have thoroughly been elaborated in the original article.

39 2. METHODOLOGY

40 To be included in this review, studies/overviews must meet the following inclusion criteria: 1)
41 conducted/written no sooner than 1991 and published as full articles in journals and books; 2) each
42 article meets the specific characteristics of its according type of therapies.

43 Articles were retrieved from 3 electronic databases: MEDLINE/PubMed, Google Scholar and Science
44 Direct, the search terms differ according to their listed categories, as shown in Table 1. The authors
45 do not claim to have included all of the existing pertinent literatures on the issue because of
46 restrictions on database access. Also, the authors are well aware that studies of plant oils efficacy in
47 medicinal practices are limited due to the overwhelming number of presence herbs in comparison to
48 the inadequate amount of researches. The searches thus do not wholly reflect the potentials of plant
49 oils at present but shall work as a guide to more directed approaches. In so doing, a total of 47
50 articles were examined and reviewed.

51 **Table 1. Keywords used for literature searching**

Therapies	Keywords
Moisturizers, emollients and barrier protection	Pruritus, itch, plant oils, moisturizers, emollients, transepidermal water loss, barrier protection, itch, dry itch
Antihistamines	Itch, pruritus, antihistamine, H1/H4 antagonist, pruritus, allergy, bronchodilatory effect, plant oils, essential oils
Topical neuromodulators	Itch, pruritus, local anesthetic, sciatic nerve, plant oils, essential oils, antispasmodic effect, capsaicin, menthol
Topical cannabinoid	Itch, pruritus, plant oils, essential oils, phytocannabinoid, CB1/CB2 agonists, anti-inflammatory effects

52 3. RESULTS

53 3.1 Moisturizers, emollients and barrier protection

54 There has been various studies on the efficacy of moisturizers as part of pruritus' treatment plans [4–
55 6]. In brief, they do not treat itch by targeting the causes but alleviate the symptoms by hydrating the
56 skin, enhancing barrier function and decreasing transepidermal water loss (TEWL). With high
57 percentage of essential fatty acids, especially linoleic acid, plant oils are suggested to have such
58 therapeutic abilities [7,8]. This is of essential need for patients suffering pruritus who seek for an
59 inexpensive, temporary therapy, especially for a good night sleep.

60 Although plant oils are both diverse and abundant, only a selective few possess moisturizing ability
61 while merely over a handful of them has been scientifically proven. A prominent candidate would be
62 virgin coconut oil (VCO), which originates from fresh coconut milk and is left unrefined. Evangelista *et*
63 *al.* [9] studied the effect of VCO comparing with mineral oil on pediatric atopic dermatitis (AD) patients.
64 The 5 mL topical application on full body of each assigned oil lasted for 8 weeks and results were
65 analyzed based on the SCORAD index, TEWL, and skin capacitance values. Overall, VCO showed
66 superior efficacy in all three categories, which was suggested to result from its skin penetratory as
67 well as anti-inflammatory activities. Another research by Agero AI and Verallo-Rowell VM [10] studied
68 the effect of VCO as a moisturizer in xerosis patients and concluded that “coconut oil is as effective
69 and as safe as mineral oil”.

70 Sunflower seed oil has been tested as an effective moisturizing agent, either in direct topical
71 application [11] or being incorporated as an active ingredient [12,13]. In the former study, sunflower
72 seed oil massage on a mouse model significantly induced a rapid recovery of TEWL, as well as
73 exhibiting a long lasting effect in comparison with other vegetable oils. On the other hand, the latter
74 studies examined the efficacy of 2% sunflower oleodistillate (SOD) emollient in skin barrier disorders,

notably atopic dermatitis. SOD is a byproduct of the original oil extracted by molecular distillation, which in turn bears a 10-fold increase in its unsaponifiable content. Results showed that both studies proved the effectiveness of 2% SOD emollient and suggested its use in the management of related skin disorders.

In a review by A. Lubbe and R. Verpoorte [14], several plant oils were enlisted for their use in cosmetic products, notably as incorporated in moisturizers and emollients, such as castor oil (*Ricinus communis*), jojoba oil (*Simmondsia chinensis*), almond oil (*Prunus dulcis*), sesame oil (*Sesamum indicum*), avocado oil (*Persea Americana*), apricot kernel oil (*Prunus armeniaca*), rapeseed oil (*Brassica napus*), linseed oil (*Linum usitatissimum*), sunflower seed oil (*Helianthus annuus*), palm oil (*Elaeis guineensis*), and coconut oil (*Cocos nucifera*). Also, 7 African seed oils having moisturizing effects were reviewed in a paper by I. Vermakk *et al.* [15] with varying amounts of scientific evidences. *Sclerocarya birrea* seed oil, or marula oil, being the most scrutinized, underwent clinical tests of "skin hydration, transepidermal water loss and increase in skin smoothness". It was also shown to reduce itching and skin redness. Other seed oils listed were *Adansonia digitata* (baobab), *Citrullus lanatus* (Kalahari melon), *Schinziophyton rautanenii* (manketti/mungongo), *Trichilia emetica* (mafura butter) and *Ximenia americana* (sour plum). Their efficacies in improving defected skins were mainly due to the high essential fatty acid content in each oil's components.

Despite not being well-researched as the aforementioned, aloe vera extract, rose absolute oil (RAO) and St. John's wort extract (*Hypericum perforatum*) still hold sufficient evidences for their therapeutic effects. A randomized vehicle-controlled study on 20 volunteers assessed the effect of different *A. vera* extract's concentrations resulting in a notable improvement in skin hydration [16]. RAO was proved to be capable of enhancing keratinocytes differentiation and accelerating skin barrier recovery on mouse models by the use of immunohistochemistry [17]. St. John's wort, on the other hand, is valued for its main active ingredient – hyperforin, which was shown to stimulate differentiation markers as well as exhibiting superiority over the vehicle when incorporated into hypericum-cream (1.5% hyperforin) in topical treatment of mild to moderate AD [18].

3.2 Antihistamine

The group of Görnemann [19] assessed the influence of the essential oil of *Lippia dulcis* Trev. on histamine/carbachol – induced contractions in guinea pigs' bronchial segments. Concentration-response curves were constructed accordingly, with atropine, mepyramine as positive controls, DMSO as a negative control and the essential oil (50-100 µg/mL) as our protagonist. Acquired data showed that the histamine curve was shifted to the right significantly under the influence of 100 µg/mL of the essential oil ($P < 0.05$), along with a depression in the maximal histamine response (from 106 ± 6 to $64 \pm 7\%$). The authors thus suggested a noncompetitive antagonistic activity to histamine exerted by the essential oil of *Lippia dulcis* Trev. with camphor, its main constituent, suspected to be the main acting ingredient.

The essential oil of *Carum copticum* was screened for antihistaminic activity in a study by Boskabady and Shaikhi in 2000 [20]. Guinea pigs' tracheal chains were incubated in indomethacin, propranolol hydrochloride, atropine sulfate in 3 sets of experiments for histamine acid phosphate-induced contractions, followed by the construction of a cumulative log concentration-response curve. The results showed competitive antagonism effects of the oil at histamine H1 receptors, which was projected to be resulted from muscarinic blocking effects. Thus, the authors speculated that such activity may largely be attributed to α -pinene, a constituent of the oil, whose anti-cholinergic activity was examined in a study by Bogats and Ephstein, 1959. Differences in H1 receptor blocking effects of extracts and oil from *Carum copticum* may be due to incoherency in extraction methods, as indicated in the study.

The group of Boskabady [21] extended their research on the essential oil of *Carum copticum* by evaluating the relaxant effects on contracted guinea pig tracheal chains of its 4 different fractions collected after each 25 mL of the elution (with solvent being mixtures of petroleum ether and chloroform). Of the 4 fractions, fraction 2 was presumed to be carvacrol as indicated by their similar R results. The data suggested volume-dependent bronchodilatory effects of fractions 1, 2, 3 of the oil, with the latter two being more potent. Besides, β_2 – adrenergic stimulatory effect was not observed in the fractions' relaxant actions, indicating carvacrol's seemingly major role in the oil of *Carum copticum*'s bronchodilatory activity

The essential oil of German chamomile flower [22] was obtained from the flower's ethyl acetate extract and briefly tested for its ability in alleviating compound 48/80-induced itch. The results showed a concentration-dependence effect, with 100-300 mg/kg, p.o., as a safety range for motor activities.

Kim and Cho (1998) [23] evaluated lavender oil's therapeutic effect in type I hypersensitivity in mice and rats. The oil was applied topically and intradermally in experiments of ear swelling response and PCA induction in order to test mast-cell mediated skin allergic reaction. Its effects on both tested subjects were proved significant as compound 48/8-induced ear swelling response in mice and anti-DNP IgE-induced PCA in rats were inhibited. Besides, the potency of topical lavender oil was deemed more significant than that of the intradermally applied oil in the 2 types of tests. Moreover, histamine release from peritoneal mast cells was effectively blocked by the said oils in application. The authors also suggested an action on membrane permeability of the oil to be the protagonist of its examined effects.

M.H. Boskabady and A. Moghadas [24] conducted a study of *Bunium persicum* antagonist effect at histamine H1 receptors in incubated guinea pig tracheal chains under 3 different conditions: (1) 1.4 μ M indomethacin, (2) indomethacin, 1 μ M propranolol, and 10 nM atropine, and (3) indomethacin and propranolol ($n = 8$). The results were interpreted from recorded responses by a kymograph. Overall, the authors suggested that *B. persicum* showed antihistaminic effects on H1 receptors, which could be resulted from the stimulatory effect on β – adrenergic receptors.

Hajare *et al.* [25] performed a similar but much simplified study on the antihistaminic activity of *Piper betel* leaf by examining its ethanolic extract and essential oil. The experiments were set up using isolated guinea pig tracheal chain and ileum models, both of which could indicate the tested activity. At 100 μ g/mL each, *P. betel*'s extract and essential oil were able to inhibit histamine-induced contractions of the 2 pig's body parts. Such ability occurred in a concentration-dependent manner.

José Henrique Leal-Cardoso *et al.* [26] performed a study on the ability of *Croton nepetaefolius*'s essential oil (EOCN) to interfere with histamine-induced activities by examining its electrophysiological effects in celiac neurons. Although this does not resemble the mechanism of antihistamine, it was suggested from the study that EOCN block histamine's effect by affecting midway events in the signal transduction pathway following H1 receptor activation. This is of noteworthy consideration since there is little evidence for plant oil's antihistaminic activity, and regarding EOCN as an alternative which produces a comparable effect should yield more options for pharmacists. However, more studies should be conducted before the thought can be realized.

3.3 Topical neuromodulators

3.3.1 Local anesthetics

Lidocaine and prilocaine, two well-known local anesthetics, exert their antipruritic effects by blocking voltage-gated sodium channel, thus stabilizing nerve sensory fibers. Following the logic, essential oils of the like should act on those channels or blocking the compound action potential (CAP) generated by sodium influx.

The action of the essential oil of *Alpinia zerumpet* (EOAZ) was addressed by Leal-Cardoso's group [27] by measuring changes in the compound action potential (CAP) parameters – CAP peak-to-peak amplitude and CAP conduction velocities - on sciatic nerves dissected from rats. The oil also exhibited a dose-dependent effect on CAP, as well as a complete blockade by the 2000 μ g/mL concentration. The CAP peak-to-peak amplitudes and conduction velocity were reduced. EOAZ-washed out nerves recovered to normal values during the latter 180-min period. Such records suggested that EOAZ may possess local anesthetic property, which is compatible to previous studies on the property of its constituent – 1,8-cineole [28] and other essential oils' constituents having similar structures such as eugenol [29] or α -terpineol [30]. The authors also proposed that EOAZ had a slow-course action on nerve cells, leading to probably higher effects on CAP parameters if the exposure time was more than 3 hours. Furthermore, other than tackling neurons' membranes, EOAZ could affect cells intracellularly because of the observed slow changes. In conclusion, EOAZ were found to be active on nerves in a concentration-dependent manner, blocking CAP generation and conduction.

In 2006, PM Lima-Accioly *et al.* [31] examined the same influences on nerve cells but by a different essential oil – that of *Croton nepetaefolius* (EOCN)) – and its constituent 1,8-cineole. The experimental design remained unchanged with two additional measurements – chronaxie and rheobase. Regarding peak-to-peak amplitude and conduction velocity, substantial reductions were observed in the applications of 500, 1000 $\mu\text{g/mL}$ EOCN ($n = 6$) and 4, 6, 8 mmol/L 1,8-cineole ($n = 6$). At the end of the 180-min bathing time, rheobase and chronaxy values were recorded to have increased. Such data tellingly suggested the dose-dependent manner of EOCN and 1,8-cineole's ability to block nerve excitability. However, such inhibitory effect was more potent in 1,8-cineole in a lower dose (0.81 mmol/L) than that of EOCN (4 mmol/L), as well as a total recovery after the washout was only exhibited by the substance. Thus, the authors proposed that 1,8-cineole alone could be insufficient to wholly take responsibility in EOCN's actions on nerve excitability, and the roles of other constituents such as E-caryophyllene and bicyclogermacrene should be considered. Another remark made was the EOCN and its main constituents' mechanism of action, which was postulated to interfere with sodium channel activation, as well as exhibiting intracellular alterations such as axonal metabolism due to the slow time-course reaching for steady-state conditions. Nevertheless, more lights have to be shed on the subject before any convincing conclusions are to be made.

Another essential oil extracted from *Croton zehnteri* (EOCz) and its main constituent - anethole was found to possess local anesthetic activity using the same experimental procedure [32]. With concentrations ranging from 0.1 to 10 mg/mL, the tested substances reduced peak-to-peak amplitude and CAP conduction velocity in a dose-dependent manner, as well as increasing chronaxie and rheobase values. At 0.60 mg/mL concentration, EOCz and anethole completely inhibited all CAP waves. Comparison test regarding lidocaine, EOCz and anethole was conducted, showing similar modes of action among the three. Overall, the author group proposed that EOCz may act as a local anesthetic agent, and its effects could be traced back to anethole – the main constituent.

A similar experimental strategy was applied to address the essential oil of *Lippia alba* (EOLa) and citral (its constituent – 75% of the oil in this specific study) 's actions on rat's nerve excitability [33]. Results showed that there was a preference of both EOLa and citral for the second CAP component, which comprises of small myelinated motor fibers. A lower threshold concentration for citral ($n = 6$) – 10 $\mu\text{g/mL}$ - than that of EOLa ($n = 7$) – 30 $\mu\text{g/mL}$, together with a shorter time course to achieve full blockade (90 min in comparison to 180 min of EOLa) indicated more powerful depressor effects of the constituent. Regarding the CAP components' conduction velocities, EOLa and citral both reduced this parameter in a dose – dependent manner. However, it is noteworthy that only at 300 and 100 $\mu\text{g/mL}$ for each respectively, the CAP amplitudes were completely blocked to the point that the conduction velocities could not be measured. Chronaxy and rheobase values also increased at 60 $\mu\text{g/mL}$ EOLa and 30 $\mu\text{g/mL}$ citral, indicating a hindrance to the generation of action potential. The data showed a correlation between EOLa's effects and its constituents for there was only a mere gap between the 2 threshold concentrations, along with a high (75%) amount of citral in the tested sample. It is clear that among the essential oils of *Alpinia zerumbet*, *Croton nepetaefolius* and *Lippia alba*, the third one exhibited changes on conduction velocities at the lowest concentration. The authors proposed EOLa to possess local anesthetic activity due to its blockade of nerve excitability, and that EOLa and citral may behave similar to linalool and carvacrol by acting directly on Na^+ channels.

Lavandula augustifolia, a flowering plant native to the Mediterranean, is known for its therapeutic use as a relaxant, especially in the oil form. In this regard, Ghelardini and Galeotti *et al.* [34] sought to elucidate the proposed local anesthetic activity of such essential oil. Using the *Citrus reticulata* Blanco and *Citrus limon* (L.) Burm.f.'s essential oils as negative controls, procaine and lidocaine as reference drugs, as well as linalool and linalyl acetate as targeted subjects, the authors conducted rat – phrenic hemidiaphragm test and rabbit conjunctival reflex for proof of anestheticsity. In the former experiment, the 3 tested subjects, within the range of 0.1 – 1000 $\mu\text{g/mL}$ were capable of eliciting reductions dose-dependently in the electrically evoked contractions *in vitro*, to the point of complete elimination of the contractions. The former experiment carried out *in vivo* saw a rise in the number of stimuli needed for provoking the reflex when treated with the oil (30 – 2500 $\mu\text{g/mL}$) and its constituents. Since linalool and linalyl acetate exhibited similar behaviours to that of *L. augustifolia*'s essential oil, it was proposed that they may take responsibility for the oil's activity. On the other hand, although the mechanism of action of *L. augustifolia* was not a direct study's interest, the authors speculated a relation to antimuscarinic activity regarding to observations in the rat phrenic hemidiaphragm test. Also, a blockage of Na^+ and/or Ca^{2+} channels resulting from the local anesthetic activity was proposed.

Linalool-rich rosewood oil (87.7%) was tested for its influence on neuronal excitability by the sciatic nerve model as described above [35]. Data showed irreversible blockades by various concentrations of the oils with their respective increasing inhibiting powers, from 75% at 2 $\mu\text{g/mL}$ to 95% at 100 $\mu\text{g/mL}$. The question whether the effect occurs exclusively due to the oil's main constituent is still open. Besides, it was suggested from the study that rosewood oil exert its activity probably by acting on voltage-dependent Na^+ channels.

3.3.2 Menthol

Menthol, a terpene derived from mint species, has been found to possess many therapeutic effects, especially when serving as a neuromodulator. It exerts anti-pruritic [36], anesthetic [37], anti-noiceptive [38] activities by primarily acting on thermo receptors, desensitizing TRPV1 receptors as well as showing weak kappa-opioid receptor agonistic activity. Yet, menthol-containing oils such as peppermint or eucalyptus oil [39] have yet been studied much upon, particularly the anti-itch property. Still, there laid hopes for the said oils in the treatment of itch as they contain menthol, a multipotent compound, and their anti-inflammatory, antinociceptive potency have been proved, which share several related neurotransmitting pathways to the anti-itch activity.

3.3.3 Capsaicin

Unlike menthol, which activates cold receptors in the peripheral nerves, capsaicin exerts its effect on the heat receptors, or the TRP family of proteins to be specific. Thus, the application of topical capsaicin on human skin initially causes a prickly sensation often associated with pain or itch, and subsequently "numbs" the nerves if prolonged action is maintained. In other words, desensitization of noiceptors is the main mechanism of the extract that leads to its use in treating painful syndromes. That being said, patients with itching conditions are thus frequently prescribed capsaicin for symptom alleviations, because pain and itch share related transmitting pathways.

3.4 Topical cannabinoids

α -Amyrin, a pentacyclic triterpene, was proved to exert agonistic effects on CB1 and CB2 receptors with varying degrees of potency. It is also a main constituent of *Ocimum basilicum* L. essential oil (OBV), whose topical anti-inflammatory activity was tested in the study of Festus BC et al., 2013. By the application of doses of 50, 100, 200, and 400 $\mu\text{g/ear}$ on a modified acute topical edema model, OBV and 3 other tested subjects, *Ocimum basilicum* L. hexane extract (OBHE), *Ocimum gratissimum* L. essential oil (OGV), *Ocimum gratissimum* L. hexane extract (OGHE), were screened for anti-inflammatory activity. Statistical analysis showed that all of them possessed inhibitory effect on edema at the concentration of 50 $\mu\text{g/ear}$, and they were dose-independent. Notably, OBV seemed to be the most potent of all, even more effective than hydrocortisone, a control. The authors later elaborated that varying degrees of activity may be due to different extraction methods, which resulted in diverse anti-inflammatory constituents. Furthermore, OBV bears additional substances, especially α -amyrin, that were shown to exhibit said activity [40] which may explain its highest potency. Thus, *Ocimum basilicum* L. essential oil might act as a CB1/CB2 agonist as well as an antipruritic agent because it possesses topical anti-inflammatory activity and α -amyrin as a main constituent.

Another phytocannabinoid that fully agonizes CB2 receptors is β -caryophyllene, found in both cannabis and non-cannabis plant. In particular, *Farfugium japonicum* essential oil bearing 12.26% of β -caryophyllene was screened for topical anti-inflammatory activity in a study of Kim et al., 2008 [41] by determining nitric oxide (NO) and prostaglandin (PGE_2) productions in lipopolysaccharide (LPS) – activated RAW 264.7 macrophages. Inhibition of production was present in both tests, and the authors suggested such potency be restricted not only to the oil's toxicity but also its active constituents. Also, test of safety for human skin application of the oil was conducted on human dermal fibroblast, which further shed light on the possibility of incorporating this oil in topical treatment of anti-inflammatory – related diseases. That being said, *Farfugium japonicum* essential oil may be utilized as an antipruritic agent for its speculated CB2 agonistic effect.

The essential oil of *Bupleurum frutescens* exerted anti-inflammatory effects in the test of carrageenan – induced hind paw edema, administered orally [42]. Its main constituents are hydrocarbon, notably β -caryophyllene (30.55%), a prospective CB_2 agonist.

286 Passos *et al.*, 2007 evaluated *Cordia verbenacea* essential oil and its main constituent – (–)*trans*-
287 caryophyllene for anti-inflammatory effects [43]. Both were administered orally in the carrageenan –
288 induced rat paw edema, and showed significant improvements at 300-600 mg/kg for the oil and 50
289 mg/kg for the active compound. Tellingly, (–)*trans*-caryophyllene is also called β -caryophyllene

290 Alkylamides found in the *Echinacea* genus can act as full agonist on CB₂ receptors, as reported by
291 Sharma *et al.*, 2015 [40]. Also, the essential oil of *Echinacea purpurea* L. was examined for its anti-
292 inflammatory activities by tests of xylene-induced ear edema and egg albumen – induced paw edema
293 in mice, with results showing significant improvements in the middle and high dose groups[44].

2942. 4. DISCUSSION

295 This compilation of 51 articles shows that plant oils are indeed of practical use in itch alleviation. To
296 be more specific, plant oils as moisturizers or skin-hydrating agents are the most studied and applied,
297 with oils from 21 species assessed both in clinical trials and cosmetic uses. The second category,
298 local neuromodulators, though only has its tested subjects performed in *in vitro* condition, the results
299 were tellingly unanimous in that the six oils examined may well act as local anesthetizing agents. In
300 contrast, the remaining two categories, topical antihistamines and topical cannabinoids, have very few
301 findings with mere speculated therapeutic prospects. However, on a positive outlook, the fact that
302 they could act similar to their synthetic counterpart reserves room for future conducts.

303 In a more detailed note, the studies' design (i.e tests of TEWL, skin capacitance values, etc.) of the
304 moisturizer category rests upon the role of essential fatty acids in hydrating and improving skin barrier
305 functions. As vegetable oils, in this particular case, are high in said substances, especially in linoleic
306 acid (Table 2), the results ensued that they acted accordingly to their main components. Moreover,
307 linoleic acid is also a precursor of arachidonic acid, which in turn undergoes oxidation to produce
308 eicosanoids, whose subfamilies such as prostanoids partake in mediating symptoms of inflammation.
309 In that regard, vegetable oils may be superior to synthetic moisturizers in alleviating itch, which shares
310 related pathway to topical inflammatory conditions, by in part soothing the inflamed skin. However, the
311 aforementioned studies either had few sample sizes (18-25 patients) or were carried out *in vitro*.
312 Furthermore, there have not been exact formulations of the topical creams nor systemic reviews on
313 whether their therapeutic effects well excel over other on-the-counter products.

314

319

The use of antihistamine in alleviating itch is debatable despite being frequently prescribed. According to Klein's systematic review in 1999 on the efficacy of antihistamine in alleviating pruritus, few studies had been conducted to assess the said effect, and none of them obtained a well-designed model for accurate assessment. Nevertheless, *in vitro* studies showed the correlation of histamine H1, H4 receptors, activation to itch evocation, thus inferring the role of antihistamines as antipruritic agents, with the postulated superior efficacy of the H4 counterpart [45,46]. Besides, H1 receptor antagonists were also proved to expedite damaged barrier skin regeneration [47], whose effects if unfixed might as well cause dry skin – induced itch. In writing this part of the review, the authors could not search for a substantial amount of direct *in vivo* studies on essential oils alleviating itch by acting as antihistamine, hence replacing them with related evidences. More specifically, as H1, H4 histamine receptors also are present in the lungs, noses and skins, studies on anti-allergic, anti-spasmodic and bronchodilatory oils passed the inclusion criteria. In so doing, the oils of *lippia dulcis* Trev., *carum copticum*, german chamomile flower, lavender, *B. persicum*, *piper betel*, *croton nepetaeifolius* were listed for their antihistaminic activities on various experimental designs, all of which antagonize H1 receptors. Of the 6 oils examined, *lippie dulcis* Trev. and *carum copticum* were found to largely owe their antihistaminic activities to the main constituents, carvacrol and camphor, respectively. On the other hand, although no studies on essential oils exerting H4 antagonistic activity were found, their potentials in the field is indispensable as H4 antagonists clearly excel over their H1 counterparts in alleviating itch.

Local anesthetic activity of the 6 oils examined was assessed by measuring the following physiological parameters: peak-to-peak amplitude (PPA), compound action potential (CAP), chronaxie and rheobase. Strictly speaking, PPA and CAP represent nerve conduction, while the latter stand for nerve excitability. Regardingly, decreasing values of PPA and CAP along with increasing values of chronaxie and rheobase are signs of an anesthetized nerve. Following that logic, rosewood, lavender, EOCz, EOLa, EOAZ, EOCN oils were proved to exert depression on nerve excitability within a pharmacological range and in a concentration-dependent manner. Such activity was postulated to stem from the interference of sodium channel activation, which is a characteristic of local anesthetics drug like lidocaine. In other words, these essential oils not only behave similarly to their synthetic counterparts, but also possess potency at concentrations that are appropriate for human intake, thus might be considered for novel drug synthesis. Of the 6 oils examined, only EOCN and rosewood oils' effects were irreversible after the washout, indicating their impressive potency. Also, a pattern among the aforementioned studies surfaces up when one examines them closely: each essential oil's local anesthetic activity is partially or wholly (in the EOLa's case) linked with its main constituents, which possess similar or stronger potency. Henceforth, although studies of the activity on oils are minor, researchers may extrapolate other potential oils from their accordingly main constituents. In fact, abundant researches have been carried out to examine these extracts's anesthetic activity such as linalool, menthol, terpineol, eugenol, carvacrol, 1,8-cineole, estragole, β -carophyllene, etc. Moreover, researchers could as well predict a plant's local anesthetic activity by examining its analgesic, sedative and antispasmodic effects, as can be inferred from the studies where 6 oils possess similar activities. In addition, Table 3 enlists essential oils and their according main/active constituents in this category.

360 **Table 3. Essential oils and their main/active constituents having local anestheticity**

Essential oils	Main/active constituents	References
<i>Alpinia zerumpet</i>	1,8-cineole (20.57%)	[27]
		
<i>Croton nepetaefolius</i>	1,8-cineole (24.98%)	[31]
		
<i>Croton zethneri</i>	Anethole (85.7%)	[32]
		
<i>Lippia alba</i>	Citral (75%)	[33]
		
<i>Lavandula angustifolia</i>	Linalyl acetate (43.6%) Linalool (31.5%)	[34]
		
Rosewood oil	Linalool (87.7%)	[35]
		

361 **All the images of Table 3 were drawn using ChemDoodle 2D Sketcher.*

362 Being a prospective therapy, studies on ligands of cannabinoid receptors not only showed improved
 363 results in itch-relating diseases [48,49] but also generated no observed side effects. Its mechanism
 364 has not been officially agreed upon, yet many are convinced that small particles agonizing CB1/CB2
 365 receptors may be the protagonists. Fortunately, aromatic oils with their tiny molecular components
 366 excel in targeting channels or other parts that are impenetrable to normal oils, and CB1/CB2
 367 receptors stand as no exceptions. In fact, classes of phytocannabinoids and noncannabinoid plant

constituents have been categorized in the last few years as prospective ligands of the said receptors. Since limited researches on phytocannabinoid's antipruritic effect are present, the authors opted for studies concentrating on essential oils that contain the reported constituents and exert antinoiceptive and/or anti-inflammatory potency, which share related pathway with pruritus. In so doing, the essential oils of *Ocimum basilicum* L., *Farfugium japonica*, *Bupleurum frutescens*, *Cordia verbenacea* and *Echinacea purpurea* L. were enlisted in this category since they produce anti-inflammatory effects and bear α -amyrin, β -caryophyllene and alkylamides as their main constituents, respectively. These nano-sized molecules, as aforementioned, can act as full CB₁/CB₂ agonists. Although studies on phytocannabinoid and non-cannabinoid plant constituents have recently been robust, its essential oil aspect and topical therapeutic effects have not been deeply delved into. Largely, researchers take their interests in treating retroperitoneal inflammation[50,51], or the efficacy of the plants' ether extracts. This, however, sets more opportunities for researchers to elucidate on the potential effects of CB₂/CB₁ agonists contained in essential oils for the alleviation of itch.

5. CONCLUSION

Itch poses as a challenging predominant symptom of skin diseases that calls for the attention of specialists. Among the alternatives to treatments, plant oils have proved its efficacy in alleviating pruritus. To be more specific, the use of plant oils as moisturizers has been recognized in this reviewed as the most promising among the 4 therapies mentioned. The rests, antihistamine, topical neuromodulators and cannabinoid require further research to confirm their practicality in the matter.
