2	
3	Breeding Methods to Obtain
4	Superior Genotypes of Okra
-	
5 6 7 8	ABSTRACT
o	The culture of okra, although little known, exhibits an interesting trade in relation to other vegetable crops. This is mainly due to its sensorial and nutritional qualities. However, despite their importance, there are still almost no breeding programs aimed at obtaining superior genotypes, much of this is due to complications in the use of breeding methods for this culture. The objective of this work <u>was to</u> prepare a literature review for improved accuracy improvement of methods for obtaining superior genotypes of okra. Based on the present literature the choice of the most appropriate method for each characteristic can result in superior lineages.
9 10 11	Keywords: Abelmoschus esculentus, precocity of culture, yield of pod, quality of fruits.
12	1. INTRODUCTION
13 14 15 16 17	The okra ( <i>Abelmoschus esculentus</i> L. Moench.) is a vegetable of great social and economic importance for several regions of the world, being mainly cultivated in the tropics, subtropics and hot regions of temperate zones [1-2]. In Brazil, the okra finds ideal conditions for its cultivation in the region Northeast and Southeast of the country [3].
19 20	The productivity of cultivated okra crop varies between 15 and 22 tonne/ha, under Brazilian conditions. It can be cultivated in <u>for</u> good yield throughout the year. Such culture presents attractive
21 22 23 24	characteristics in cultivation and consumption, such as ease of management, relatively fast vegetative cycle, high food value, great utility and high profitability. Despite the importance of this culture, the search so much in general, as in the area of plant breeding is still incipient [4].
25 26 27 28 29 30 31 32 33	Thus it becomes necessity to develop early varieties, productive and fruit quality for farmers, as an alternative to hybrid varieties, mainly due to the low level of technology that the producers have. According to [5], besides good production, plants with greater maturity or more precocious are desirable in cultivars of okra, since they exceed the vegetative phase in a shorter time, reducing the period of exposure of the plant to the attack of diseases and pests. This advantage is reflected in the possibility of commercialization of the product before cultivars of normal cycle, being able to obtain better prices. In this context, researchers [6] report that the development of new varieties is one of the technologies that increases productivity and stabilizes production, without additional costs to the farmer.
34 35 36 37 38 39 40	For the development of a well-structured breeding program, it is essential to know how to choose the best parents in relation to the characteristics of interest for breeding [7]. The use of methodologies for this purpose represent excellent tools to aid the breeder in obtaining promising segregating populations for obtaining good lines. According to [8] several methodologies the selection genitors can be used, among them the diallel crosses <b>allow</b> , which allow the obtaining of basic information regarding the parents to initiate a program of genetic improvement for the culture of the okra, so much for the production of self-pollinating varieties, as for the production of hybrid varieties. In possession
41 42 43 44	of the best combination of parents, an appropriate improvement method should be used to drive the segregating population, for <b>the possible</b> obtaining <b>of</b> good progenies, that can be evaluated in preliminary tests, until arriving at a new variety [9].

**Comment [DSG1]:** Consider rewriting this sentence. Not clear

1

45	The objective of this work was to <b>perform</b> <u>review</u> a literature <b>review</b> to support the establishment of a future	
46	breeding program for the production of early <b>varieties</b> , productive and quality <u>varieties</u> through consultation of	
47	scientific articles that deal with the subject in question.	
48		
49	2. GENERAL ASPECTS OF CULTURE OF OKRA	
50		
51	The okra belongs to the family Malvaceae, being the only relevant oleraceous culture within this	
52	family, presenting great importance for regions with semi-arid conditions because it is a vegetable	
53	adapted to this condition. It is a crop exploited mainly in Asia, Africa, America and in the	
54 55	Mediterranean regions [10].	
56	The origin of okra is still unclear, with most authors citing Africa, possibly in Ethiopia [11], in every way	
57	this culture presents important centers of genetic diversity, which include West Africa. India, and	
58	Southeast Asia [12-13].	
59		
60	The cultivated species of okra is considered polyphyletic, since it is believed that its origin came from	
61	more than one species. The main hypothesis regarding this information is the variation of the number	
62	of chromosomes in the genus that presents about 10 known species [14-15].	
63	In relation to subconstice, on previously reported there is considerable variation in the number of	
64 65	chromosomes and also in levels of ploidy both among the species of the genus Abelmoschus, how	
66	much within the cultivated species, it has been observed more frequently in <i>Abelmoschus</i> , esculentus	
67	(L) Moench $2n = 130$ , however, some authors such as [14], reported the existence of $2n = 72$ , 108.	
68	120, 130 and 144 chromosomes.	
69		
70	Depending on the location, this culture is known by different denominations: gumbo, gombô, okra,	
71	ladys <u>f</u> dinger (English), bhindi or bhendi (Indian), bamyah or bamiat (Arabic), quimbombo (Spanish)	
72	[16].	
73	The akra is considered an annual plant, which is characterized by being shrub, of erect postage and	
75	semi-woody stem that can reach three meters of height the plant shows the greenish or greenish	
76	coloration with reddish areas, despite this size, in this plant lateral branches can still occur, which are	
77	stimulated by management practices in the cultivation, such as the use of larger spacings [17]. The	
78	leaves are large, with deeply cut limbus, lobed and with long petioles [17].	
79		
80	The okra is a culture that has its propagation via seeds, being more usual its planting in direct sowing, where it is considered on intermediate appoint with 4,10% group pollipation, their flowers facilitate the	
82	where it is considered an intermediate species with $4 - 19 \times 1005$ -pointiation, then nowers tachinate the crossing process by the fact that they are validate and large (A to 8 cm in diameter) the anthesis	
83	occurs most often between 06:00 hs and 10:00 hs.	
84		
85	The fruits of the okra measure about 25 cm, with five locules, and hairy, are capsule type, plump,	
86	presenting circular or pentagonal cross-section, its production occurs even when the plant is small	
87	both on the main stem and on the sides, depending on the cultivar, there is the production of medium	
88	and short truits with protructing angles or with almost circular section, in general have the pyramidal	
09	shape, with average yield of ou seeds [16].	
91	The development of the culture of the okra is quite variable in relation to the duration of the vegetative	
92	and reproductive periods, being very influenced by the cultivar used., Hhowever, in general, the	
93	vegetative stage lasts from the emergencey until about 60 days after sowing, then begins the	
94	reproductive stage that goes up to 120 days after sowing. Lit is worth emphasizing that the planting	
95	season influences the cycle of this culture intensely, because the reports that the fruiting period	
96	exceeded 200 days [3].	
97	The harvest of the fruits is performed several times, the expect observed should be seft as tenderfruit	
90 90	with bright green coloration. In hot times the harvest begins with five to six days after the opening of	
100	the flower, and in the winter with six to seven days after the opening of the flower. Harvesting is	
101	usually manual, at least twice a week, being ideal to harvest on alternate days [16].	

103 Despite the importance of the okra, there are few institutions that work with this culture, and this gets 104 worse when is taking into account breeding programs. 105 3. IMPROVEMENT FOR PRECOCITY, PRODUCTION AND QUALITY 106 107 108 For the improvement of any crop, it is necessary to gather in the varieties, a series of not only 109 productive characters, but also such the of quality, to meet the demands of producers and consumers. In the 110 okra, characters such as precocity, production and quality are indispensable. 111 112 The selection of early materials of okra facilitates the cultivation of this vegetable in regions scarce of 113 financial and natural resources. Early cultivars may be part of the variety management strategy, 114 because these if compared with cultivars of normal cycle, the influence the marketing of the product, because its obtaining is faster, reflecting the possibility of marketing strategies, and in the field makes 115 it possible to obtain a product of better quality, reducing the exposure of the okra to the biotic and 116 117 abiotic intemperies [5]. 118 The researchers [19], report that the importance of the precocity variable of harvest, is evidenced 119 120 besides the agronomic advantages, because the early harvest facilitates the hiring of labor at the 121 beginning of the harvest which is a critical period, this being a great economic advantage, because it 122 allows economic return at the beginning of the activity. 123 The use of early cultivars allows the concomitant increase of fruit production [5], besides this increase 124 by planting, early cultivars allow a greater amount of cultivation of this vegetable, allowing greater 125 return over time. It is worth noting that despite this interesting relationship to arrive at a productive and 126 precocious variety, these characters are strongly influenced by the environmental component [20], 127 thus requiring, according to [5] of improvement methods that use greater control of the environment, 128 such as those presenting progeny testing, the selection according to [21], should be performed using 129 130 populations with large numbers of individuals, so that the maximum of recombinations occurs due to 131 the large number of chromosomes of this species. Besides the possibility of the improvement of the okra by means of the obtaining of segregating populations, there is also the possibility of exploitation 132 133 of vigor of hybrid in F1. 134 135 In plant breeding, in addition to meeting productive needs, by means of the attributes of precocity and 136 productivity in okra, it is necessary to develop quality products, which are well accepted, being the 137 fiber content and the coloring of the okra fruit, two important parameters in this segment. 138 139 The okra fruits should be marketed new and tender, because with its complete development occurs the increase of the fiber content until a certain limit, the ideal is that the harvest point of the okra is 140 141 when the fiber content is less than 6.5%, being tender and having a size of 10 to 14 cm, after these 142 values, the in nature consumption of this vegetable becomes inadequate [16]. The fiber content and coloration varies greatly between the different okra cultivars, being interesting, their evaluations in 143 breeding programs. In general, the cultivars of North America have a higher fiber content than the 144 145 indigenous cultivars [2]. 146 4. DIALLELIC ANALYSIS IN THE CHOICE OF PARENTS 147 148 The choice of parents, not always the most productive agronomically are those that have the best 149 150 combination capacity to be used in breeding programs. In this way, the genetic analysis of parents is 151 used to identify the best combinations for the precocity, production and quality [22-23]. 152 In the genetic analysis for the choice of parents [8], cites several methodologies, among them, diallel 153 154 crosses are the most widely used in almost all cultivated species in obtaining promising segregating 155 populations, and this stage is fundamental to succeed in the subsequent stages of the breeding 156 program [24]. 157 Depending on the complexity, there are several types of dialleles which have been used: 1. Complete 158 159 or balanced dialleles - are those that include the hybrids in generation F1 or F2 or any generation 160 among all pairs of combinations of the parents; 2. Circulating dialleles - in which the parents are 161 represented in the hybrid combinations in a smaller number of crosses than in the other types; 3.

3

Comment [DSG2]: consider reframing to

Comment [DSG3]: not clear what you

make it more understandable

want to say

162 Unbalanced dialleles - are those that some programmed hybrid combinations are not obtained; 4. 163 Incomplete dialleles - are those that the progenitors are represented by a variable number of crossings; 5. Partial dialleles - those involving two groups of parents [8-25]. 164 165 166 According to [25], there are some more used methodologies of analysis of a diallel, among them can be cited: [26] that evaluates the effects and sums of squares of effects of the general and specific 167 168 capacity of combination; [27] evaluating the effects of varieties and varietal heterosis; and the proposal by [28] that informs on the inheritance of the character, genetic values of the parents and the 169 170 selection limit. 171 Partial diallel analysis has the objective of studying the obtaining of favorable phenotypes that are 172 found in different groups of parents, not being of interest the combinations within each group, as well 173 as the factorial model proposed by [29-30]. 174 175 176 According to [8], the use of the methodology of diallel crosses, allows the selection of parents from the estimates of General combining ability and specific combining (GCA and SCA), seeking to identify 177 178 those with high estimates of these parameters, thus, segregating populations of these parents are expected to have a high average and expressive genetic variability, these parameters are 179 fundamental for the extraction of lineages in segregating populations. In general, the general 180 181 combining ability (GCA) is very useful for directing future hybridization works, because it is expected 182 that individuals with a high value of this parameter will allow good hybrid combinations with the other 183 parents [31]. 184 185 The okra is considered an autogamous plant, in the improvement thereof the self-pollinated methods 186 can be used or can exploit the heterosis. For both situations, it is necessary to know how to select the 187 best parents that allow the best combinations [32]. According to [9], the heterosis this or hybrid vigor 188 is the increase of progeny performance in relation to the parents, due to the crossing between 189 contrasting individuals, this phenomenon in the culture of the okra was studied by some authors [33-190 34-35], which verified productive increase in several characters of the culture. 191 5. METHODS OF DRIVING OF SEGREGATING POPULATION AND PRELIMINARY 192 **PROGENY EVALUATION** 193 194 With the variability generated from the best combination of parents, one of the appropriate methods of 195 conducting segregant populations should be used for autogamous plants for the extraction of 196 197 advanced lines. According to [9], the methods are classified in two ways, first in those that do not 198 separate the phase of endogamy and selection, which are mainly included the mass method and the 199 genealogical method, in which starting of generation  $F_2$  when variability already exists the selection 200 starts. Secondarily the other methods, which separate these two phases. 201 Particularly the genealogical method known as the pedigree method was proposed by Hjalman 202 203 Nilsson, being very popular for the development of lines of autogamous species. But over the years it 204 has been replaced by other methods such as the single seed descent method [9]. Even so, that is of great importance and is used until the present day. In this method the whole genealogy of the plants 205 206 is annotated to support selection, providing accurate kinship relationships among progenies [36]. 207 According to [37], the method involves the following phases: 1. Crossing between two or more 208 209 varieties; 2. Selection of a large number of individual plants in generation F2; 3. Planting of the progenies of the individual plants by selecting between and within until the generation  $F_4$  and  $F_5$  in 210 which selection can be initiated only among the progenies, by the attainment of the accentuated 211 212 homozygosity; 4. Carry out the production and quality tests for two or three years to choose the progenies that will constitute the new varieties. 213 214 215 6. CONCLUSION

#### 216

- Based on the literature, several important elements were identified in relation to okra breeding and 217
- 218 culture, taking into account the aspects from the correct selection of the parents to the early
- 219 evaluation of the lineages.
