Urban extension in Calabar: A remotely sensed assessment

6 Abstract

1 2

5

Urban places in the developing world, like the advanced world, are experiencing 7 8 unprecedented extension or growth, although mostly in an uncontrolled manner. Calabar is no exception to such urban extension, with notable sprawl, especially with increased 9 10 densification within the city and expansion along the fringes. This study aimed at assessing land use/ land-cover (LULC) changes in Calabar between the year 2000 and 2018. 70m 11 ETM+ Landsat imagery of both years was acquired from the Landsat Look platform. The 12 13 imageries were subjected to an unsupervised classification using the Iso Cluster and 14 Maximum Likelihood Classification tool. Measurements were done on the raster outputs to 15 allow for a comparison of the LULC statistics which assisted in identifying the pattern 16 extension in Calabar over the period. Results showed that in the year 2000, out of the total 17 164.3 square kilometers (sqkm) covered by the city, the extent of urban built-up was 28.7 sqkm and 62.2 sqkm for green areas. However, in the year 2018, the urban built-up area 18 19 increased to 44.8 sqm and green areas witnessed a reduction to 52.7 sqkm. Wetlands also 20 reduced in the area by 5.2 sqkm. The spate of urban extension and encroachment into green 21 fields and wetlands in Calabar is obvious, and somewhat inevitable, as shown by this study. It 22 is thus recommended that necessary measures be taken by relevant government agencies to 23 monitor and manage this gradual extension, such that the development is organised and 24 sustainable.

Keywords: Urban extension, land use, land-cover, geographic information systems, remote
sensing, Calabar.

27 Introduction

Globally, land cover today is altered principally by direct anthropogenic factors like agriculture and livestock raising, forest harvesting and urban and suburban construction and development (Owoeye & Ibitoye, 2016). Due to rapid human activities, the earth surface is being progressively altered in such a manner that man's existence on earth and his use of land is being greatly affected. The fast pace of urbanization has been shown to be a serious global problem and is more evident in most of the developing countries. There is also every indication that the trend will continue, adding approximately two billion people to the urban population of the presently less-developed nations in the next 30 years (United Nations Environment Programme, 2002)

The world is becoming increasingly urbanised, with 45 percent of the population already living in the urban areas in the year 2000. The projection then was that half of the world will live in urban areas by 2007 (Arnfield, 2003). It was also estimated that by the year 2025, 60 percent of the world's population will live in cities (United Nations Population Fund, 1999). The land transformation has been asserted to be one of the most important fields of humaninduced environmental transformation (Fasal, 2000).

43 Urbanization is one of the several anthropogenic activities that impact on land use/land cover. 44 Urban population has been growing more rapidly than rural population worldwide. 45 particularly in developing countries (Lambin et al., 2003). It is measured by the rate at which the spatial extent of an urban settlement extends. In most countries, urban growth is 46 47 recognized as a crucial phenomenon of economic growth and social change, as it offers increased opportunities for employment, specialization, production, goods and services 48 (Odjugo, Enaruvbe and Isibor, 2015), which in turn initiates a large number of people 49 50 migrating from rural to urban areas (Abebe, 2013).

Several empirical studies (Zhao, Dickson and Tian, 2004; Nanda, 2005) have shown that unplanned changes of land use due to urbanisation become a major problem. Most land use changes occur without a clear and logical planning activity and without attention to their environmental impacts. In metropolitan cities, major flooding, air pollution as well as deforestation, urban growth, soil erosion, desertification, are consequences of mismanaged planning without considering the environmental impacts of development plans.

57 Calabar is the capital city of Cross River State, in the southern region of Nigeria. The city lies between Longitudes 8°18'00"E to 8°24'00"E, and latitudes 4°54'00"N to 5°04'00"N, 58 sandwiched between Odukpani Local Government Area (LGA) to the north, the Calabar River 59 to the west, Great Kwa River to the east, and the creeks of the Cross River as it empties into 60 61 the Atlantic Ocean in the South (Figure 1). The Metropolis covers an approximate land area 62 of 137.039 square kilometers (sqkm), and had a population of 328,878 in 1991, and 375,196 in 2006 according to the National Population Commission (NPC), and a projected population 63 of 529,362 in 2015 (Njoku, Okon, Itu and Ahwen, 2017). Calabar has witnessed observable 64

urban extension over time. The built-up area continues to extend outward and has consumed
prior agricultural and wetlands at a break-neck pace. Hectares of green areas are now covered
by concrete and asphalt, as new roads are created and existing ones are extended. Over 5000
hectares of greenery has been taken over by built-up activities in the Ekorinim, Esuk Utan,
Edim-Otop, Anantigha, and Ikot Effanga areas of the metropolis (Atu et al., 2012).

As the population of Calabar increases, so also is the desire to accommodate these population 70 71 thresholds through urbanisation. The extension of the urban area in Calabar has resulted not 72 only in depletion of natural resources but is deterioration of the environment. The unregulated 73 and haphazard growth of urban development has adversely affected Calabar's ecosystem 74 (Offiong & Eteng, 2014). This study is aimed at assessing spatial and temporal land use and land-cover changes in Calabar between the year 2000 and 2018, using remotely sensed data 75 76 and GIS techniques. GIS-based multi-temporal land use data and analyses provide a historical 77 vehicle for determining and evaluating long-term changes in land use due to urbanisation. 78 The collection of remotely sensed data facilitates the synoptic analyses of changes on the earth surface at local, regional and global scales over time (Wilkie and Finn, 1996). 79

82 Materials and Methods

The methodology of this study incorporated a reconnaissance survey, data acquisition, data processing and data analysis. The reconnaissance survey aimed at getting the researcher acquainted with the existing physical characteristics of the study area. A knowledge that was very useful for the selection of training sites before classification. The types of data used include Landsat imageries which were obtained from *Landsat Look* platform. Their attributes are presented in **Table 1**. Relevant literature materials were obtained from textbooks, journals and other existing literature that are related to the research problem.

94

95 Image processing and classification

96 There was no need for georeferencing the images since they were already ortho-rectified. The 97 images were clipped with the boundary data of Calabar using the clip tool in the ArcMap 98 platform. However, the images were geometrically corrected to the Universal Transverse 99 Mercator (UTM) Zone 32 North coordinate system on the same platform. To detect changes 100 in the land use/cover at different years, post classification comparison of the change detection 101 techniques was used.

102 The boundary data of Calabar metropolis was used to clip the Landsat imagery. The clipping 103 helped to remove the extents outside the boundary of the satellite imagery (depicted in false colour in Figure 2 and 3). After clipping, Earth Resource Development Assessment System 104 105 (ERDAS) imagine software was used for the pixel-based classification. The images were 106 subjected to an unsupervised classification using the Iso Cluster (IC) and Maximum 107 Likelihood Classification (MLC) spatial analyst tool. The IC combines the functionalities of 108 the IC and the MLC, while the MLC performs classification on a set of raster bands using a 109 signature file from the IC tool as the input for MLC. The ArcMap software was afterwards 110 used for the final processing of the ERDAS outputs.

111 The classified raster output was converted to vectors (polygons) to allow for measurements to be done. The area coverage of each of the LULC classes was measured in sqkm, for each of 112 113 the years under consideration, using the calculate geometry tool in the same ArcMap 114 platform. A comparison of the land cover statistics assists in identifying the change in 115 sqkm/percentage, trend, and rate of change in Calabar over the period. In this study, in line 116 with Anderson, Hardy, Roach and Witmer (1976) the land-use/land-cover classification 117 scheme in (Wakirwa, 2015), the various land-use/land-cover (LULC) types are modified and 118 generalised into 4 classes within the study area as presented in Table 2.

125 **Results and Discussions**

126 Land use and land cover scenario in Calabar from 2000 to 2018

To assess the LULC situation of Calabar in the past and present, the LULC analysis was executed. Tables, maps, and charts were used to illustrate the LULC status quo in Calabar during 2000 and 2018 respectively. As symbolised by the legend, the colour brown is used to represent the built-up area, the light green for green area, the blue colour represents water bodies and the dark green, the forest areas.

As observed from the analysis outputs presented in **Table 3**, and **Figures 4-5**, there were evident changes in the LULC of Calabar during the 18-year period. From the year 2000 to 2018, there was little change in the extent of the water bodies, with only a slight decrease of 0.9 percent. The Calabar and Great Kwa rivers are tidal rivers, mostly influenced by their closeness to the Atlantic Ocean. The rivers are minimally influenced by urban activities, as the wet land bordering them still shield the rivers from direct urban extension impacts.

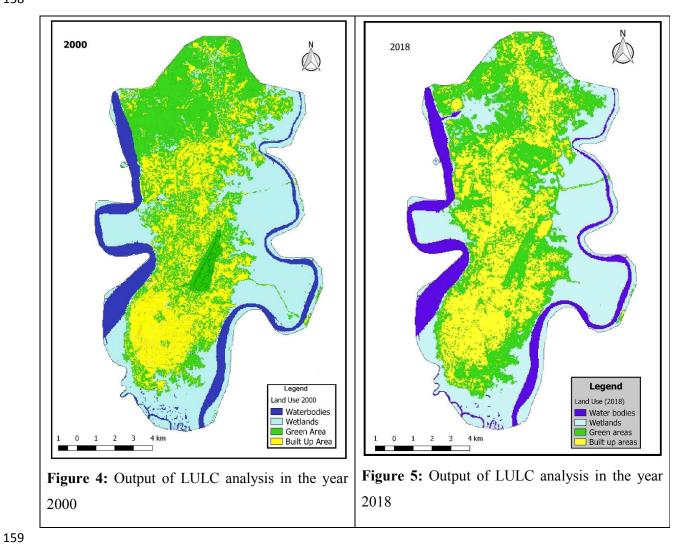

138

139 Within the same period under review, built-up areas increased by 16.1 sqm, with a coverage of 28.7 sqkm in the year 2000 and 44.8 in 2018. As pictured in Figure 5, the city visibly 140 extended mostly to the northern fringes with new developments in the 8th mile, Ikot Nkebre, 141 142 Adiabo, and other areas in the northern fringes. There was also no significant extension in the 143 southern area, which houses the Calabar South Local Government Area (LGA). The direct impact of the urban built-up extension is on the green areas, which saw a reduction of 9.5 144 145 sqkm from an initial 62.2 sqkm in the year 2000. The wetlands on both sides of the city were also reduced by 5.2 sqkm. The extension in the urban build-up follows from the swelling 146 147 population and increased socio-economic activities within the study area. Notably, the urban extension evident in these fringe areas of Calabar are haphazard and uncoordinated, thus 148 149 requiring the attention of relevant agencies to ensure sustainable urban development in the 150 area.

163 164

165 **Conclusion and Recommendation**

Typical to urban centers, urban extension in Calabar has been triggered by increased human activities, resulting in LULC changes. The impacts of these changes are worrisome in the face of uncoordinated planning policies and implementation. The application of remote sensing and GIS provided quantification, estimation and understanding of LULC changes in Calabar. There was an apparent extension in the urban built-up area of Calabar with the greenery mostly suffering the impacts of the extension.

172 From the findings of this study, the following is recommended:

- i. Land use planning should be instituted and implemented in Calabar to ensure that the
 usage of land, especially in the fringe, is sustainable. This effort should involve the
 sectoral integration of the relevant state ministries, boards, and bodies of the Calabar
 Municipal Council.
- 177 ii. Intensive sensitisation should also be embarked upon and pursued holistically, with a
 178 view to ensuring that the inhabitants of the study area understand the negative
 179 effects and consequences that are associated with uncoordinated landuse
 180 development.
- 181 iii. Deliberate efforts such as the declaration, reservation, and preservation of the
 182 ecologically fragile greenery and wetland areas of Calabar should be instituted and
 183 logically pursued by the government.
- iv. Finally, smart development of diverse-mixed land use should be encouraged, to reduce
 the rapid rate and large amount of urban land being converted for construction of
 homes, offices and commercial buildings.
