

**Original Research Articles****NEUTRONICS STUDY OF NIRR-1 FUELLED WITH 19.75% UO<sub>2</sub> MATERIAL USING VENTURE-PC AND SCALE 6.1 CODES****ABSTRACT**

A comprehensive neutronics analysis using VENTURE-PC and SCALE 6.1 computer codes system has been performed for the core conversion study of Nigeria Research Reactor-1 (NIRR-1). The computed reactor core physics parameters include: group neutron fluxes profiles, power density distributions and neutron flux distributions. The number of active fuel pins used for this analysis is approximate 200 pins, which show that the fuel pins have been reduced to about 58% when compared with the present Highly Enriched Uranium (HEU) fuel (UAl<sub>4</sub>-Al) of 347 pins. These reductions in the number of fuel pins has given room for more moderators in the core and hence increase the number of hydrogen available to thermalize the neutron in the potential 19.75% UO<sub>2</sub> fuelled core for Nigeria Research Reactor-1 (NIRR-1). The diffusion theory based calculated values of thermal flux profiles for the vertical as well as for the horizontal radial directions has been found to agree well with similar calculations using different nuclear analysis tools. The results obtained will qualify uranium dioxide (UO<sub>2</sub>) fuel as the potential material for future Low Enriched Uranium (LEU) core conversion of Nigeria Miniature Neutron Source Reactors (MNSRs).

**INTRODUCTION**

Uranium dioxide (UO<sub>2</sub>), a ceramic fuel is presently the most commonly used nuclear fuel for both research and power reactors. Uranium dioxide material is the fuel of choice for most reactors due to its high melting point (2800°C), high neutron utilization, excellent irradiation stability, exceptional corrosion resistance in conventional coolants, good fission product retention, no phase change up to the melting point, compatibility with cladding (Zircaloy and stainless steel), ease of fabrication, and high specific power and power per unit length of fuel pin (Sundaran and Mannan, 1989; Sunghwan, 2013). UO<sub>2</sub> has a fabrication density of 10.3g/cm<sup>3</sup> and offers a relatively high uranium loading of about 9.1g/cm<sup>3</sup>. The use of highly enriched uranium (HEU) material in research reactors has leads to a set of inevitable proliferation risks. HEU fuel is the last remaining civilian application of a direct-use of material, which is easily utilize in a nuclear

32 explosive device (Franz et al., 2005). NIRR-1 is one of the world MNSR reactors that still uses  
33 HEU as fuel and therefore presents a potential nuclear proliferation threats to global security.  
34 NIRR-1 core was initially designed by China Institute of Atomic Energy (CIAE) with computer  
35 codes HAMMER and EXTERMINATOR-2 and 90.2% enriched  $UAl_4$ -Al as fuel (FSAR, 2005).  
36 HAMMER and EXTERMINATOR are the first set of codes used to solve reactor physics  
37 problem using diffusion theory method followed by WIMS and CITATION codes (Balogun,  
38 2003). To model and analyze the NIRR-1 core a 2-D (r,z) neutronics models was developed  
39 using the recent version of diffusion theory codes (VENTURE-PC and SCALE 6.1). VENTURE-  
40 PC consists of VENTURE module (which solves reactor physics problems based on the  
41 multigroupneutronics finite different diffusion theory) and EXPOSURE computational module  
42 plus several other processing modules. It is a recent version of diffusion theory based  
43 deterministic code (White and Tooker, 1999) that can be used like CITATION (Balogun, 2003)  
44 to perform neutronics analysis for the NIRR-1 system. The VENTURE-PC code is used to  
45 generate the group fluxes profiles, power density distributions and criticality information within  
46 the Nigeria Research Reactor-1 core. It is also used to compute the effective multiplication  
47 factor, the neutron flux distributions at different location within the core of the proposed 19.75%  
48  $UO_2$  material for core conversion studies of NIRR-1 from HEU to LEU. SCALE code provides a  
49 “plug-and-play” framework with 89 computational modules, including three deterministic and  
50 three Monte Carlo radiation transport solvers that are selected based on the desired solution  
51 (Salawu, 2012). The SCALE 6.1 code is used to generate the cross section libraries used in this  
52 work. Achieving the core conversion of NIRR-1 to operate on the LEU fuel would be a useful  
53 step toward, an effort to reduce and eventually eliminate the civil use of HEU material in  
54 research reactors. This work attempt to design a system with a higher performance in the area  
55 such as high neutron fluxes, higher fuel burn-ups, longer fuel cycle length and other reactor  
56 design parameters as compared with a similar study that uses 12.5%  $UO_2$  material as the fuel.

57

58

## 59 MATERIALS AND METHOD

60 Reactor physics codes are typically used to support the performance of the core as well as to  
61 provide results used in the system thermal hydraulic codes for accident analysis. The  
62 VENTURE-PC code is used in this work to compute the group fluxes profiles, power density

63 distributions and criticality information within the Nigeria Research Reactor-1. The SCALE 6.1  
 64 code is used to generate the cross section libraries, perform the multigroup neutron flux  
 65 calculations, as well as provide k-infinity from the one dimensional criticality calculations for the  
 66 proposed 19.75% UO<sub>2</sub> material for core conversion studies of NIRR-1. The core of NIRR-1  
 67 contains fuel cage, fuel pins (which serves as the main energy source), control rod with a guide  
 68 tube (which is provided to facilitate the movement of the control rod), three dummy rods and  
 69 four tie rods. The specific reactor physics calculation for the generation of the cross section  
 70 libraries in this reactor required a collection of three cell models for the primary core elements,  
 71 one each for the fuel rod, the control rod and materials outside the core regions. The top and  
 72 bottom plate of the fuel cage is replaced with zirconium material in the LEU core. About nine  
 73 different modules of SCALE code system is used to perform the cross section libraries  
 74 development and these modules include AJAX, WORKER, CRAWDAD, BONAMI, CENTRM,  
 75 PMC, PALEALE, XSDRNPM and WAX modules (Salawu, 2012). The volume fraction ( $f_i$ ) for  
 76 the zones in the fuel cell were determined by first calculating the volume of each zones and then  
 77 divide each values by the total volume of the equivalent fuel cell. Table 1.0 shows the calculated  
 78 region volume fraction for the zones in the NIRR-1 fuel cell model.

79 Table 1.0: The region volume fraction ( $f_i$ ) for the zones in the NIRR-1 fuel cell model (with 200  
 80 active fuel pins)

| S/N | Region    | Volume (cm <sup>2</sup> ) | Tot. vol. (cm <sup>2</sup> ) | Vol. fraction ( $f_i$ ) | Tot. vol. fraction |
|-----|-----------|---------------------------|------------------------------|-------------------------|--------------------|
| 1.  | Fuel      | 0.1452                    | 2.0918                       | 0.0694                  | 1.0000             |
| 2.  | Clad      | 0.0924                    |                              | 0.0442                  |                    |
| 3.  | Moderator | 1.8542                    |                              | 0.8864                  |                    |

81  
 82 The molecular weight of uranium and atom densities of various isotopes in Zircaloy-4 in the  
 83 proposed LEU fuel material was calculated from the relations:

$$\frac{1}{M_u} = \sum_i \frac{w_i}{M_i} \tag{1.0}$$

$$N_i = \frac{w_i \rho N_A}{M_i} = \gamma_i \times N_{mix} \tag{2.0}$$

$$\gamma_i = \frac{\text{Atoms of } i}{\text{Total atoms}} \tag{3.0}$$

86 Where,  $M_u$  is the molecular weight of natural uranium in the fuel material,  $N_i$  is the region atom  
 87 densities,  $N_A$  is the Avogadro's number,  $\rho$  is the density of Zircaloy-4,  $w_i$  is the weight percent  
 88 of i and  $M_i$  is the molecular weight of i.

89 The results of the atom densities of various natural isotopes present in the individual nuclide of  
 90 Zircaloy-4 are used to obtain the material composition data (atoms/b-cm) for the LEU fuel cell  
 91 model as shown in table 2.0. This result is then used to calculate average homogenized atom  
 92 density ( $N_{iz}$ ) for the LEU fuel material in the water mix region for the Zircaloy-4.

93

96

97 The effective multiplication factor values generated by the VENTURE-PC code for different  
 98 shim thickness were used to compute the reactivity worth of the top beryllium shims (see table  
 99 3.0), the value for  $k_{eff}$  at critical height is 1.0112886. The reactivity worth and the control rod  
 100 worth may be expressed mathematically as:

$$\text{Reactivity, } \rho = \frac{k_{eff} - k_{eff} \text{ at critical height}}{k_{eff} \text{ at critical height}} \quad (4.0)$$

$$\text{Control rod worth} = \text{Reactivity worth} + \text{Shutdown margin} \quad (5.0)$$

101 Where the shutdown margin is the negative reactivity the reactors core present when the control  
 102 rod is fully inserted (Henry et al., 2014).

103 Table 3.0: Shim thickness, k-effective and reactivity for the NIRR-1 2-D model

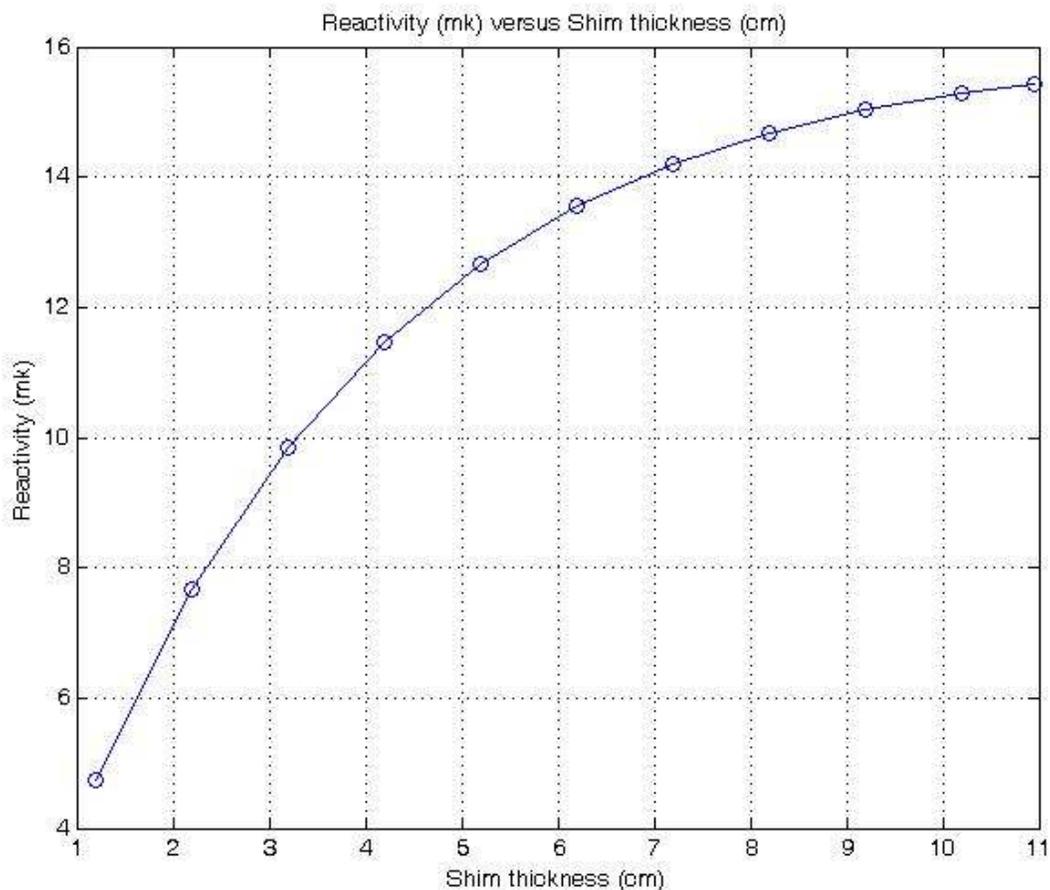

| S/N | Shim thickness (cm)<br>(Top Beryllium thickness) | Reactivity (k) |
|-----|--|----------------|
| 1.  | 1.2  | 4.7336636e-3   |

104

105 The SCALE 6.1 code was used to generate the three major different cross section libraries  
 106 developed in this work.

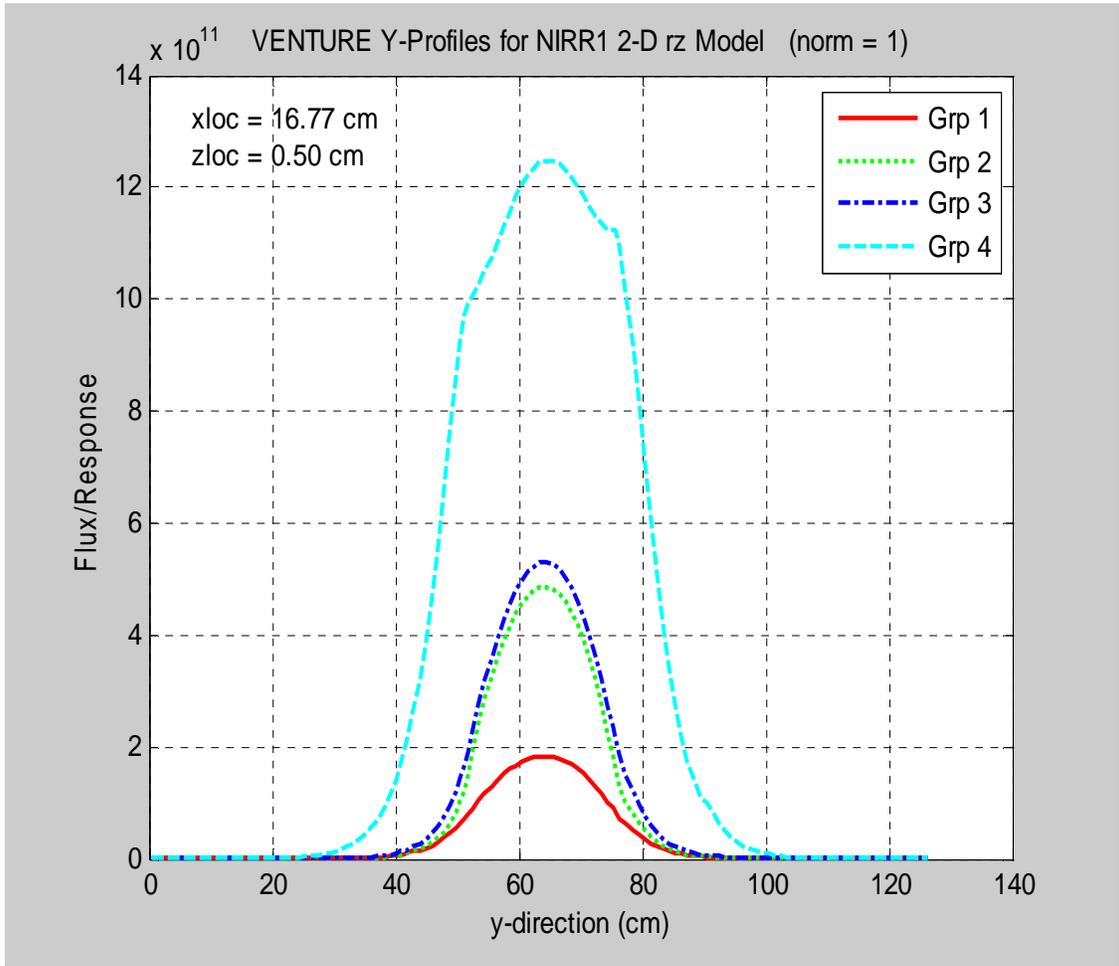

107 **RESULTS AND DISCURSION**

108 Results have been obtained for the neutronics characteristic of the projected LEU fuel (UO<sub>2</sub>-  
 109 Zircaloy-4-clad) for NIRR-1 MNSR core using the VENTURE-PC code and SCALE code  
 110 system. The proper averaged cross section used for the homogeneous model in this work was  
 111 generated using the heterogeneous fuel cell and control cell models. This model was used by  
 112 SCALE 6.1 code to determine neutron flux as a function of both space and energy for each  
 113 location in the cell model.

114  
 115 The above figure show the graph of measured reactivity worth versus shim thickness during the  
 116 off-site zero-power test for the LEU core using the VENTURE-PC code. The value of the total  
 117 control rod worth obtained for this work from the four group calculation for the LEU core is  
 118 7.23mk which is in good agreement when compared with similar results calculated by G.I  
 119 Balogun using CITATION code (Balogun, 2003), S.A Jonah using MCNP code (Jonah et al.,  
 120 2007) and S. Abdulhameed using VENTURE-PC code (Salawu, 2012). The value of reactivity  
 121 worth of the top beryllium shim was obtained for each shim thickness ranging from 1.2cm to

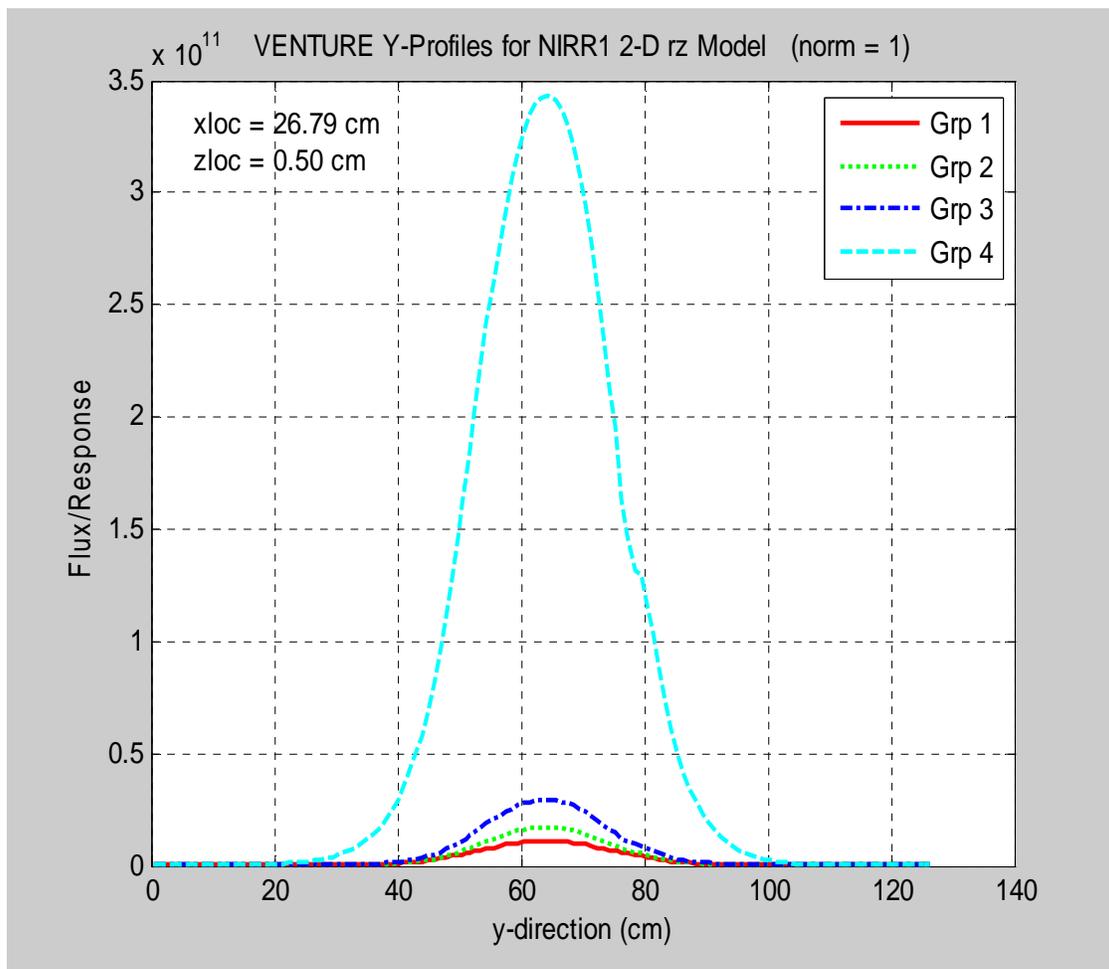

122 10.95cm. The calculated magnitudes of axial distributions of thermal, epithermal, resonance and  
123 fast neutron flux in the inner and outer irradiation channels for the proposed LEU (19.75% UO<sub>2</sub>)  
124 core for NIRR-1 were plotted as shown in figures 2.0 and 3.0 respectively. The inner and outer  
125 irradiation channels locations were selected at radial distances of 16.77cm and 26.79cm from the  
126 core center. The figures (2.0 and 3.0) also shows the computed results of the 2-D vertical Y-  
127 directed neutrons flux profiles expected at various region within the NIRR-1 (MNSRs) core  
128 model for the potential LEU core (19.75% UO<sub>2</sub>). The thermal neutrons flux level, peak power  
129 density and maximum neutron density calculated in the potential LEU core are  $1.24 \times$   
130  $10^{12} \text{ ncm}^{-2}\text{s}^{-1}$ ,  $4.31033e + 00 \text{ W/cc}$  and  $6.94535e - 6 \text{ neutron/cc}$  respectively. The  
131 calculated thermal neutron flux level is approximately equal to that of the present HEU core of  
132  $1.1 \times 10^{12} \text{ ncm}^{-2}\text{s}^{-1}$  for the present HEU core. We observed that the thermal neutrons flux  
133 level in the potential LEU core is slightly lower when compared with a similar neutrons flux in  
134 the HEU core. This implies that the total number of neutrons that were able to get to the thermal  
135 energy in the moderation or thermalization processes is lower in the LEU core than in the HEU  
136 core. Since the outer irradiation location is filled with water, we observed a symmetric neutron  
137 flux profile in this region. We did not observed any reflector peak in the high energy neutron flux  
138 as shown in figures (2.0 and 3.0), this is due to the fact that fast neutrons are not affected on the  
139 average by the reflector materials (i.e. water or beryllium) in the NIRR-1 core.

140

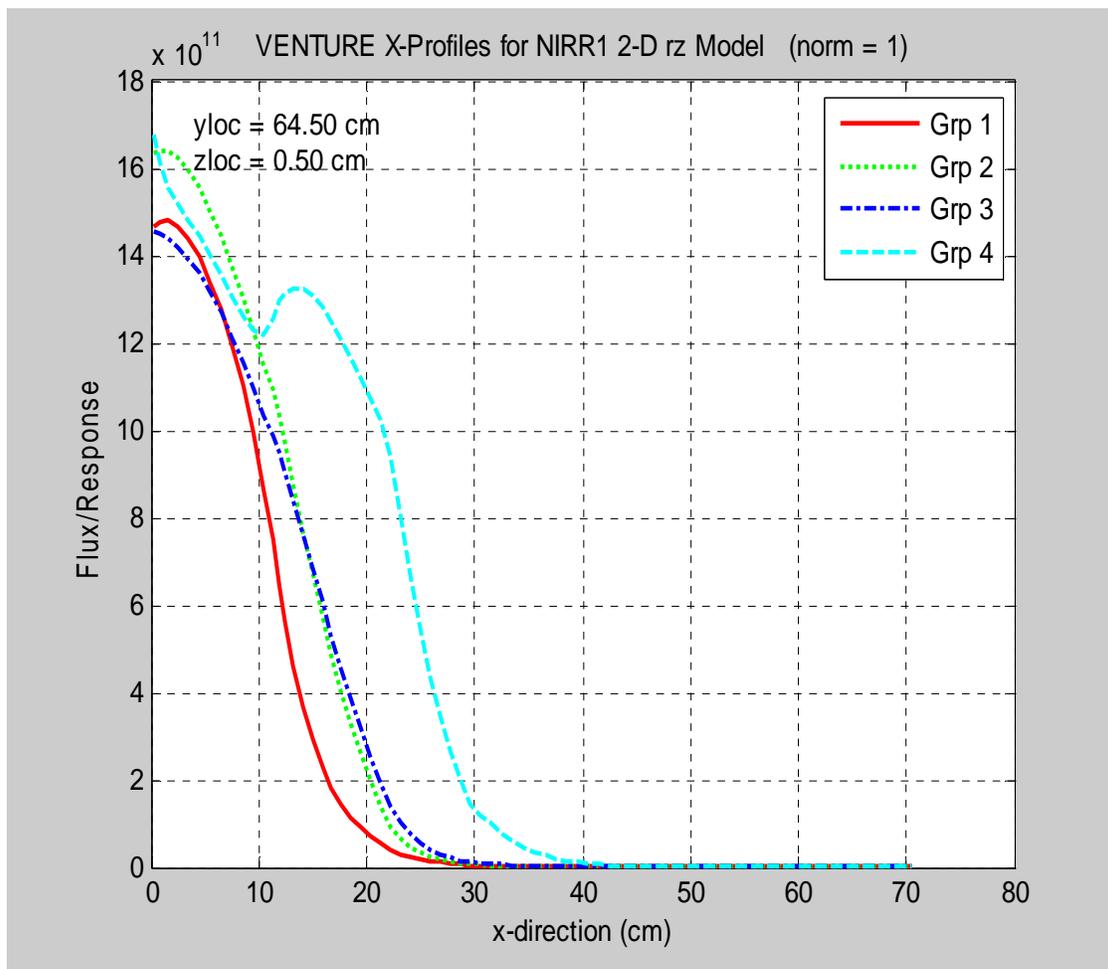

141 Figure 2.0: Vertical (Y)-directed neutrons flux profiles through the radial beryllium region for  
 142 the LEU core (19.75% UO<sub>2</sub>) for NIRR-1

143

144

145 Figure 3.0: Vertical (Y)-directed neutrons flux profiles through the outer irradiation location for  
 146 the LEU core (19.75% UO<sub>2</sub>) for NIRR-1

147

148 Figure 4.0: Horizontal (X)-directed neutrons flux profiles through the center of the LEU core  
 149 (19.75% UO<sub>2</sub>) for NIRR-1

150 Figure 4.0 shows the X-directed neutrons flux profiles starting from the center of the active fuel  
 151 region in the axial direction. The reflector peak shown in the thermal neutron flux profile  
 152 represents the effect of the radial beryllium on the thermal neutrons. The above plots reveal that  
 153 the shapes of the neutron flux in the 19.75% LEU core were similar to that of the present HEU  
 154 core of NIRR-1. The only different is that the neutron flux level is a little bit different in the  
 155 19.75% LEU core as compare to the present HEU core of NIRR-1. The detail information shown  
 156 by these plots can be of great help in selecting a region with high neutron flux for positioning  
 157 irradiation channels within the NIRR-1 reactor core. This result is consistent with the fact that  
 158 Zircaloy-4 cladding gives higher neutron economy which has positive impact on the excess  
 159 reactivity of the system.

160

161 **CONCLUSION**

162 The thermal neutron flux in the proposed LEU core (with 19.75% UO<sub>2</sub> material) is a little bit less  
163 than the present HEU core. This insignificant reduction in the flux for the same power level has  
164 shown that the NIRR-1 reactor can be fuelled with the potential 19.75% UO<sub>2</sub> (LEU) with about  
165 200 active fuel pins without any significant reduction in the NIRR-1 performance.
