Effective atomic numbers to some alloys at 662 kev by back scattering technique

4

5 ABSTRACT

6 The gamma backscattering is useful technique in determining effective atomic number of 7 backscattering material. In Gamma backscattering technique there is no direct contact with the 8 detector and material under study. So, in present work the intensity distribution of backscattered 9 photons was determined both as a function of atomic number of the target and thickness of the 10 target and then find out the effective atomic number of (PbSn, PbZn and ZnSn) alloys at 11 662KeV. These alloys were synthesized in different compositions of 82Pb, 50Sn and 30Zn 12 elements using melt quenching technique with the help of muffle furnace. The intensity 13 distribution of backscattered photons was recorded with the help of GAMMARAD5 (76 mm x 14 76 mmNaI(Tl) scintillator detector. The experimental results so obtained were compared with the 15 theoretical ones which were computed using atomic to electronic cross-section method with the 16 help of mass attenuation coefficients database of WinXCom. A good agreement has been 17 observed between theoretical and experimental results of the effective atomic numbers for the 18 selected alloys.

19 Keywords: Back Scattering, Effective Atomic number, Binary Alloys.

20 1. INTRODUCTION

21 The backscattering of photons plays important role in radiation shielding. It gives information 22 about the characteristics of the materials i.e electron density, cross sections and effective atomic 23 number of the alloys. The numbers of backscattered photons increases with increase in target 24 thickness (Udagani, 2013). In backscattering technique the sample can be accessed from the 25 same side, imaging is simple and also the depth information of the sample is possible (Majid and 26 Balamesh, 2005). In the gamma backscattering, the intensity of backscatter gamma photons 27 depends on thickness of the material and the atomic number of the material. The "effective 28 atomic number" has a physical meaning and is quite useful parameter for interpretation of 29 attenuation of X-ray or gamma radiation by a composite material. This number is also very

30 useful to visualize a number of characteristics of a material of medical, agricultural and industrial 31 interest (Singh et al., 2007). The gamma backscattering is strongly dependent on mass numbers of 32 the target atoms and effective atomic number (Z_{eff}) of the selected materials. Hence it is a useful 33 technique in determining effective atomic number (Z_{eff}) of backscattering materials (Sabharwal 34 et al., 2009a, b, c). In the present measurements effective atomic number of PbSn, PbZn and 35 ZnSn alloys was calculated by gamma backscattering. An element is mixed with another element 36 of different concentration to enhance mechanical properties such as tensile strength, hardness 37 mould ability etc. In the field of radiation physics, tin and zinc is added to lead to make the alloy 38 machine able and of high density so that it can be used as a good shielding material for gamma 39 rays. In the present work, PbSn, PbZn and ZnSn alloys are taken as these materials are easily 40 available and easy to prepare their alloy in the laboratory as the melting point of lead, zinc and 41 tin is low.

42 **2. EXPERIMENTAL DETAILS**

43 The binary alloys of Zn (Z=30), Sn (Z=50) and Pb (Z=82) were synthesized using melt 44 quench technique in different compositions using muffle furnace. The Zn (melting point: 45 419°C), Sn (melting point: 231°C) and Pb (melting point: 327°C) metalloids granules (purity > 46 99.5%) procured from Nice chemicals (P) Ltd, India were weighed in required amounts using 47 electronic digital balance (least count: 1 mg and maximum capacity: 500 g) and then heated in 48 alumina crucible at 450 °C for 10 minutes in muffle furnace and then poured quickly in cast iron 49 mould of dimensions $2 \times 2 \times 2 \text{ cm}^3$ at room temperature. The chemical composition and physical properties of the prepared samples were listed in the Table 1 and 2. The experimental work 50 carried out using ¹³⁷Cs radioactive isotopes by placing a gamma rays detector at an angle of 180° 51 52 to the incident beam. The backscattered photons were recorded using GAMMARAD5 53 (scintillator detector) of dimensions 76 mm x 76 mm having energy resolution of 7% at 662 keV 54 coupled with multichannel analyser (MCA) based on Amptek's DP5G Digital Pulse Processor for 600sec. The scintillator detector has been placed in front of ¹³⁷Cs gamma rays source at a 55 distance of 9.5 cm. In order to calibrate the detector in terms of back scattering of gamma rays, 56 57 different were recorded using calibration sources ⁵⁷Co(122keV), spectra ¹³³Ba(81keV,302keVand356keV),¹³⁷Cs(662keV),²²Na(511keV),⁶⁰Co(1173keV&1332keV) 58

59 placed at the target position. After calibration of the detector a particular incident energy photon ^{137Cs}(662keV) irradiate on the metals (13Al, 28Ni, 50Sn period and 82Pb) of varying thickness and 60 61 all the spectra were recorded with increasing thickness of selected metals (13Al, 28Ni, 50Sn period 62 and ₈₂Pb) by placing them behind the sources for the time of 600s, so as to have sufficient 63 number of counts (more than 10,000) under the area of backscattered peak (which appears at 64 200.91keV). The metals (Al, Ni, Sn and Pb) of varying thickness are used as a target placed behind the sources at a distance of 9.5 cm from gamma rays detector. The recorded spectra for 65 66 600sec were analyzed to measure the area under the backscattered photon. The contribution of 67 backscattered photons was obtained after subtracting area under the backscattered photon (with sample) from area under the backscattered photon (without sample). The schematic of 68 69 experimental set up is shown in the Fig.1

70 **3. RESULTS AND DISCUSSION**

71 The numbers of backscattered photons depend upon the atomic number of the target and 72 thickness of the target used in the experiment. So, in present work the intensity distribution of 73 backscattered photons was determined both as a function of atomic number of the target and 74 thickness of the target. To use samples of different thickness the backscattered photons at scattering angle 180° a typical backscattered peak(with sample) and a backscattered peak 75 76 (without sample) from the nickel target (thickness 19.0 mm) exposed to 662 KeV gamma 77 photons is given in Fig.2. We obtain the contribution of backscattered photons after subtracting 78 this observed backscattered peak (with sample) from backscattered peak (without sample). For 79 analysis of recorded spectrum, it is necessary to select the area under the peak. From the 80 recorded spectrum the backscattering peak area has been identified for experimental work. For 81 fixed experimental geometry the backscatter peak appears at around 200.91KeV when using the ¹³⁷Cs radioactive source. With the same experimental geometry the known metals (Al, Ni, Sn 82 and Pb) are placed at 180° with the ¹³⁷Cs radioactive source and detector assembly. The area 83 84 under the peak was recorded. The backscattering sample thickness was increased by placing 85 known metals (Al, Ni, Sn and Pb) one by one behind the previously placed known metals 86 without disturbing the experimental geometry. This procedure is repeated for targets of different 87 metals and different thicknesses to evaluate the intensity of multiply backscattered photons,

when exposed to 662 KeV gamma photons from ¹³⁷Cs source. The number of backscattered 88 89 counts, for different metals (Al, Ni, Sn and Pb) as a function of target thickness is shown in Fig.2 90 .The numbers of backscattered counts increases with increase in target thickness. A calibration 91 line is drawn between the backscattered counts and the value of atomic number of elemental targets (Al, Ni, Sn and Pb). The solid curves represent the best-fit curves through the 92 experimental data points corresponding to backscattered counts. At 180° scattering angle, the 93 94 best fitted line is shown in Fig. 3. The numbers of backscattered counts increases due to the fact 95 that an increase in target thickness results in higher number of scattering centres for the 96 interaction of primary gamma rays with target material. The backscattering of gamma photons, is 97 successfully used as an experimental technique for the evaluation of "effective atomic number" of alloys of known composition. The "effective atomic number" of an alloy Z_{eff}, provides 98 99 conclusive information about the alloy when gamma radiation are incident on it. The number of 100 backscattered counts for 662KeV gamma photons in alloys provide the "effective atomic 101 number" of these alloys using best-fit curves (Fig. 4-6) through the experimental data points for pure elements (Al, Ni, Sn and Pb) at scattering angles of 180°. Now each of the target of which 102 103 the effective atomic number is to be determined is replaced by the elemental target and again the 104 scattered spectra are recorded for the same duration of time at scattering angles of 180°. The 105 backscattered counts mentioned in Table 3 are marked on the calibration line in Fig. 4, 5 and 6 corresponding to the scattering angles 180° and the corresponding atomic number values are 106 107 interpolated along the X-axis. These values are the effective atomic number of alloys under 108 study. The effective atomic numbers of these samples are also evaluated from known elemental 109 concentration of the constituent elements using Eq. 2. The number of backscattered counts, for 110 selected alloy of different target thickness as a function of Atomic number is shown in figures 111 4-6. It have been observed that the number of backscattered counts decreases with the increase 112 in atomic numbers due to increase in number of scattering centres for the interaction of primary 113 gamma rays with target metals. . It has also been observed that the numbers of multiply 114 backscattered counts increases with decrease in atomic numbers. The measured values of 115 multiply backscattered counts using 662 KeV gamma photons from targets of selected alloys are 116 given in columns 2 of Table 3. The third and forth column in the table provides theoretical and

117 experimental values of effective atomic numbers for different composition of alloys. The 118 theoretical values obtained from WinXCom (Berger and Hubbell; 1987, Gerward et al., 2001) 119 agreed with the experimental measured values. There is a need of experiment and theoretical 120 data for gamma backscattering for alloys of industrial and nuclear interest as there is no 121 experimental data and theoretical data tables available in literature for these materials. 122 Knowledge of gamma backscattering is useful in the calculation of effective atomic number, 123 absorption and also in the field of radiation dosimetry and reactor shielding. There is deviation of 124 experimental results from the theoretical data which is due to the non-uniformity of target's 125 thickness.

Table 1 Chemical composition of prepared alloy samples

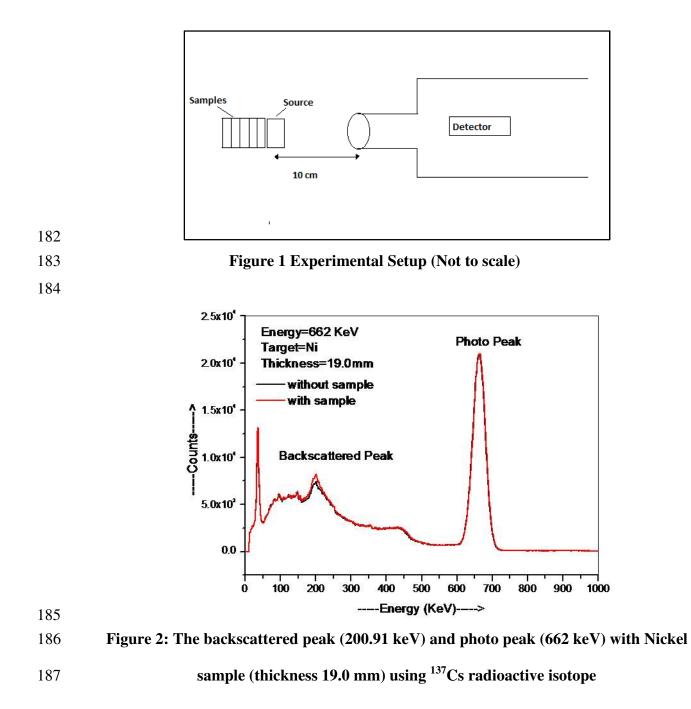

Sample No.	Selected alloys		Chemical Composition (Fractional weight)
1.	PbSn	Pb80Sn20	Pb=0.80, Sn=0.20
		Pb60Sn40	Pb=0.60, Sn=0.40
		Pb40Sn60	Pb=0.40, Sn=0.60
		Pb20Sn80	Pb=0.20, Sn=0.80
2.	PbZn	Pb80Zn20	Pb=0.80, Zn=0.20
		Pb50Zn50	Pb=050, Zn=0.50
		Pb40Zn60	Pb=0.40, Zn=0.60
3.	ZnSn	Zn80Sn20	Zn=0.80, Sn=0.20
		Zn60Sn40	Zn=0.60, Sn=0.40
		Zn70Sn30	Zn=0.70, Sn=0.30

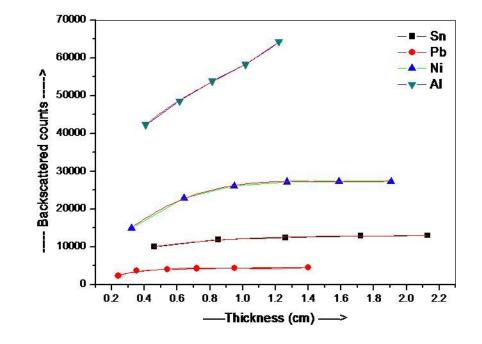

Table 2 Properties of the prepared alloy samples

Sample No.	Selected alloys		Thickness	Volume	Mass	Density
			(cm)	(cm ³)	(gm)	(gm/cm ³)
1.	PbSn	Pb80Sn20	0.75	2.94	27.19	9.25
		Pb60Sn40	0.82	3.46	27.87	8.07
		Pb40Sn60	0.877	3.22	27.07	8.41
		Pb20Sn80	0.87	3.50	24.76	7.08
2.	PbZn	Pb80Zn20	0.54	2.66	19.92	9.62
		Pb50Zn50	0.40	1.55	11.44	7.36
		Pb40Zn60	0.60	2.24	12.0	5.33
3.	ZnSn	Zn80Sn20	0.63	2.07	16.8	6.67
		Zn60Sn40	0.53	1.55	14.33	6.57
		Zn70Sn30	0.60	2.25	12.41	6.85

Sample No.	Selec	eted Alloys	No. of backscattered counts	Z _{eff} (Theoretical)	Z _{eff} (Experimental)
1.	Pb-Sn	Pb80Sn20	7258	75.7	76.64
		Pb60Sn40	9436	69.3	70.35
		Pb40Sn60	10374	63.7	63.9
		Pb20Sn80	10835	56.5	56.9
2.	Pb-Zn	Pb80Zn20	9071	72.2	71.8
		Pb50Zn50	10354	57.1	58.07
		Pb40Zn60	10208	49.9	52.5
3.	Zn-Sn	Zn80Sn20	15628	34.3	35.9
		Zn60Sn40	13356	38.4	40.65
		Zn70Sn30	13486	37	39.5
