6	Butanol as fuel	component has	some advantages	compared to	ethanol. T	he Study was
---	-----------------	---------------	-----------------	-------------	------------	--------------

- 7 aimed at isolation of different types of *Clostridium* species from the soil and screening for
- 8 their capacity for production of bio-butanol. Soil samples were collected from three different
- 9 areas in keffi. Clostridium species were isolated using Reinforce Clostridial media and
- identified using standard microbiological methods, mutation was induced in the *Clostridium*
- isolates and 16s rRNA identification techniques was used to identify the isolates.
- 12 Quantitative screening of the *Clostridium* species isolates capacity in bio-butanol was carried
- 13 out using sugar cane molasses and waste paper substrate. The result using 16s rRNA
- identification the *clostridium* isolated from old barracks was *C. acetobutylicium* the one
- 15 isolated from Amgwan kwara was C. perfringenes and C. difficile was isolated from Amgwan
- Jaba. Screening for their bio-butanol producing capacity, it was observed that *C.*
- 17 acetobutylicium produces the highest before exposing to UV light to induce mutation with
- 18 9.61± 0.94 mg/l using sugar cane molasses and 4.89± 0.19mg/l using waste paper followed
- by *C. perfringenes* 6.24± 0.61 mg/l using molasses and 3.21±0.11mg/l using waste paper.
- After exposing to UV light to induce mutation C. acetobutylicium produced  $18.03 \pm 0.17$  mg/l
- using molasses and 8.63± 0.06 mg/l using waste paper substrate follow by C. perfringenes
- 14.19  $\pm$  0.11 mg/l and 5.99  $\pm$  0.31 mg/l. From this study it was observed that C.
- 23 acetobutylicium has the capacity to produce bio-butanol and also inducing mutation will
- 24 enhance the capacity of *Clostridium* species in the production of bio-butanol.

Key: Clostridium, Bio-butanol, Molasses, Substrate

#### 1. Introduction

- 28 The rate of energy demands combined with little resources of petroleum and environmental
- 29 condition have raised a new interest in production of renewable energy from biomass, such
- 30 as agricultural crops residuals, lignocellulosic waste and from industrial waste. Apart from
- ethanol, butanol is superior in energy content, has lower volatility and is also less corrosive
- to existing infrastructure [1]. There are three main areas remaining to be sorted out if bio-
- butanol is to become a major counterpart in the bioenergy market. This includes optimizing

- feedstock utilization, reaching theoretical maximum yields of butanol and minimizing energy
- 35 consumption during separation and purification [2].
- One important driver for a bio-based economy is the exploitation of the bio-refinery concept
- 37 [3] where maximum value can be derived from the biomass through the generation of
- 38 multiple products and the effective use of process integration. Chemical pulp mills are
- 39 current examples of bio-refineries that can convert lignocellulosic biomass into energy, pulp,
- 40 cellulose derivatives, tall oil, etc. One strategy for mills to counteract competition from
- 41 tropical countries using fast-growing raw materials is to further expand the product portfolio
- into additional value-added products. Cellulose is the primary fraction utilized for chemical
- 43 pulp production, while lignin, hemicellulose and extractives could be considered as by-
- 44 products in the process. Currently lignin and a portion of the hemicellulose, and the pulping
- 45 inorganics end up in the black liquor which is concentrated and burnt in a recovery boiler to
- 46 recover the chemicals and to supply energy for a large fraction of the mills process steam
- 47 requirements. Considering the fact that lignin has double the heating value as
- 48 polysaccharides, the hemicellulose fraction solubilized during alkaline pulping represents an
- 49 underutilized resource in many mills.
- 50 One option to enhance the value of the hemicellulose is to recover this fraction prior pulping
- 51 by using hot-water extraction [4, 5]. However, despite high yields of xylene, the removal of
- 52 hemicellulose from birch wood chips prior Kraft cooking has a negative impact of some pulp
- 53 properties affecting the quality of the paper. If a decrease in pulp strength properties cannot
- 54 be accepted, another option is to recover the xylene fraction from the black liquor.
- 55 Acidification of alkaline pulping liquors precipitates lignin as well as any hemicellulose
- present in the liquor [6]. Technologies for recovery of lignin from Kraft liquors via CO<sub>2</sub>
- 57 acidification has been the subject of pilot and demonstration-scale processes [7,8] with
- 58 proposed process of generating fuels, materials, and chemicals from the lignin as well as the
- 59 opportunity for "de-bottlenecking" capacity-limited recovery-boilers. Hemicelluloses are
- typically degraded to hydroxyl- acids during Kraft pulping [9], although oligomeric xylene
- from hardwoods may be more resistant to alkaline pulping than the glucomannans which are
- 62 the predominant softwood hemicelluloses due to the protection of glucuronic acid
- substitutions against end-wise alkaline degradation, and as such, these xylenes may offer an
- opportunity for recovery and utilization as a feedstock for bioconversion. In the present
- 65 study, the aim was to produce bio-butanol using waste paper by two clostridium species
- 66 isolated in soil of Keffi.

#### 68 2.0 MATERIAL AND METHODS

- 69 2.1 Study Area
- 70 The study was carried out in Keffi, Nasarawa State, Nigeria. Keffi is approximately 68km
- 71 away from the Federal Capital Territory (FCT), Abuja and 128km away from Lafia, the capital
- town of Nasarawa State. Keffi is located at longitude 8°5'E along the Greenwich Meridian
- and at the equator and situated on longitude 850m above sea level [10].
- 74 **2.2 Sample Collection**
- 75 Three (3) soil samples were randomly collected (at the topsoil 5mm) from three different
- 76 locations of Keffi metropolis such as Angwan Jaba, Old Barracks and Angwan kwara using a
- 77 clean spoons and stored using disposable screw bottle and transported immediately to the
- 78 Microbiology Laboratory, Nasarawa State University, Keffi for isolation.

#### 79 2.2.1 Isolation of *Clostridium* species

- The isolation of *Clostridium* species from three different areas in Keffi was carried out using
- 81 spread plate method. One (1.0g) of the soil sample was suspended in 9.0ml of sterile
- 82 distilled water containing tween 80 and 7 folds dilutions were made and 0.1ml of the aliquot
- was spread on petri dishes of freshly prepared Reinforce Clostridial media containing yeast
- extract 3.0; lab-lemco powder 10.0; peptone 10.0; soluble starch 1.0; glucose 5.0; cysteine
- hydrochloride 0.5; sodium chloride 5.0, sodium acetate 3.0 and agar agar 1.0. Incubated in
- 86 anaerobic jar at 37°C for 48 hours.
- 87 **2.1.3. Identification of** *Clostridium* **species**
- 88 Cultural and morphological identifications of *Clostridium* species were carried out in
- 89 accordance with Bergey's Manual of Determinative Bacteriology [11] such as swarming test,
- gram staining test, endospore Staining egg yolk agar test, nagler test, lipase test Indole test,
- 91 catalase test and urease test.

102

- 92 2.1.4 Hank's Buffer/UV light treatment of *clostridium* isolates
- 93 Induction of mutation in *Clostridium* isolates was carried out by the modification of a method
- 94 described by [12]. Clostridia isolates were grown on Reinforce Clostridial medium
- maintained in Hank's buffer (137mM NaCl, 5.4mM KCl, 4.4mM KHIO<sub>4</sub>, 0.33mM Na<sub>2</sub>HPO<sub>4</sub>,
- 96 1.3mM CaCl<sub>2</sub>, 0.81mM MgSO<sub>4</sub>, 4.2mM NaHCO<sub>3</sub>, 1g/L glucose, pH 7.4) and were
- 97 subsequently exposed for 1 hour to ultra violet light rays from 2 white fluorescent tubes (TFC
- 98 FL-20 SD/18W Day Light). Isolates were exposed at a distance of 15cm. isolates were
- added to a mixture of 75% methanol and 25% acetic acid for 1 hour. The isolates were
- 100 subsequently incubated in 70% ethanol containing 0.07N NaOH overnight at 4 °C. Isolates
- were analyzed using 16S rRNA gene sequencing for identification.

#### 2.1.5 Extraction of bacterial DNA for 16S rRNA gene sequencing

- Eighty (80 μl) of NaOH (0.05M) was added to 20 μl of *Clostridium* isolates, were suspended
- in distilled water and the mixture was incubated at temperature of 60°C for 45 minutes, 6 µl
- of Tris/HCl (pH 7.0) were addition to achieve a final pH of 8.0. The mixture was diluted by
- 106 ×100 and 5 µl of the diluted extract was used for the polymerase chain reaction (PCR).

#### 2.1.6 PCR, gel electrophoresis, and 16S rRNA gene sequencing

- 108 Treated distilled water DNase I and PCR master mix (containing dNTPs, PCR buffer, and
- 109 Taq polymerase) were used in all PCR reactions by adding 1 U of DNase I (Pharmacia,
- Uppsala, Sweden) to 40 μl of distilled water or PCR master mix, the mixture was incubated
- at 25°C for 15 minutes, and later at 95°C for 10 minutes to inactivate the DNase I. The
- clostridial isolates, DNA extracts and control was amplified with 0.5µM primers (27F, 5'-
- 113 TGGCGAACGGGTGAGTAA-3' and 1525R, 5'-AGGCCCGGGAACGTATTCAC-3'; Inqaba
- Biotechnical Industries (Pty) UK). The PCR mixture (50 μl) contained *Clostridium* isolates
- 115 DNA, PCR buffer (10mM Tris/HCl (pH 8.3), 50mM KCl, 2mM MgCl<sub>2</sub>, and 0.01% gelatin), 200
- 116 µM of each dNTP, and 1.0 U Tag polymerase (Boehringer Mannheim, Mannheim,
- Germany). The mixtures were amplified by 40 cycles of 94°C for one minute, 55°C for one
- minute, and 72°C for two minutes, with a final extension at 72°C for 10 minutes in an
- automated 0.5 ml GeneAmp PCR system 9700 (Applied Biosystems, Foster City, California,
- USA). DNase I treated distilled water was used as the negative control. A 10 µl aliquot of
- each amplified product was electrophoresed in 1.0% (wt/vol) agarose gel, with a molecular
- 122 size marker (λ DNA Avall digest; Boehringer Mannheim) in parallel. Electrophoresis in
- 123 Tris/borate/EDTA buffer was performed at 100 V for 1.5 hours. The gel was stained with
- ethidium bromide (0.5 µg/ml) for 15 minutes, rinsed, and photographed under ultraviolet light
- 125 illumination.

130

107

- The PCR products were gel purified using the techniques developed by the National Centre
- for Bioinformatics, Islamabad, Pakistan. Both strands of the PCR products were sequenced
- twice with an ABI 377 automated sequencer according to the manufacturers' instructions
- (Inqaba Biotechnical Industries (Pty) Ltd UK) using the PCR primers (27F and 1525R).

#### 2.1.7 The pre-treatment of waste papers

- The pre-treatment of waste papers was carried out as described by [13]. The waste papers
- were thoroughly washed in water to remove dust. Waste paper substrates were pre-treated
- with 3% NaOH for 1 hour. Then, they were washed and neutralized with 0.1N HCl at pH 5.
- 134 The pre-treated waste papers were dried at 45 °C in an oven after neutralization.

#### **2.1.7.1 Acid hydrolysis**

- 136 Acid hydrolysis was done to break down cellulose into glucose units. It was carried out by
- soaking 10g of paper in different amounts of sulfuric acid 5%: 100, 200 and 300 ml of water
- for 2 hours. The mixture was autoclave at 121°C. After hydrolysis, the samples were filtered
- and centrifuged to obtain the hydrolysate product. The pH of the obtained product was
- adjusted to 5.0 by adding sodium hydroxide solution 5M

#### **2.1.8 Preparation of Molasses**

- The preparation of molasses from sugarcane was carried out as described by [14, 15]. The
- sugarcane was stripped off leaves. Its juice was extracted by cutting, crushing and mashing.
- The juice was boiled over a Bunsen burner to concentrate it, promoting sugar crystallization.
- The product of this first boiling called first syrup was used as a component of the
- 146 fermentation medium.

#### 2.1.9 Quantitative Analysis of Reducing Sugar Present in Fermentation medium

- 148 The quantitative analysis was carried out using 3, 5–dinitrosalicylic acid. The concentration
- of the sugar present in the samples was determine by adding 1cm<sup>3</sup> of 3, 5-dinitrosalicylic
- acid to 1cm<sup>3</sup> of each of the samples and boiled for 5 minutes and 10cm<sup>3</sup> distille water was
- added. The absorbance of each of sample was determined at 540nm using JENWAY 6400
- spectrophotometer. Thus, the concentration values were extrapolated from the glucose
- 153 standard curve

#### 154 2.1.10 Preparation of inoculum

- 155 The seed culture was carried out as described by [16]. The cultivated organism two colonies
- was inoculated into 10 ml of Reinforce Clostridial broth and incubated in an anaerobic jar at
- 157 37 °C for 6 hours.

#### 158 3.0 Production of Bio-butanol

#### 159 **3.1 Fermentation**

- 160 The batch fermentation was carried out as earlier described by [17] with modification. The
- 161 100 ml from the starter culture was inoculated in 900 ml of fermentation media
- 162 (enzymatically hydrolyzed waste papers and molasses) containing 25g of sugar. The
- 163 fermentation media were incubated under strict anaerobic and sterile conditions at 35°C for
- 164 96 hours.

#### 165 3.1.2 Extraction and purification of bio-butanol from fermentation broth

- 166 Extraction and purification of solvents from the fermentation broth were carried out using a
- modification of the method described by [13]. In this method, Clostridium species were used
- in the fermenter. The extracting solvent was an alkylate which was substantially free from
- impurities and had a boiling range of 118°C. The apparatus for carrying out the process
- 170 included a standard fermenter receiving fermentation broth including a carbon source and
- 171 microorganisms at a feed stream which are agitated and maintained at a desired

1/2	rementation temperature. The butanoi-containing broth was drained through a first stream
173	discharging into the upper end of an extraction column where it flowed downwardly through
174	the extractor. A second stream released a light alkylate into the bottom of the column for
175	upward countercurrent flow relative to the downward flow of the broth. The light alkylate was
176	fed from an alkylate source stream, separated in a splitter with the light end boiling in the
177	range of 1 °C. The butanol containing alkylate extract was discharged through a stream at
178	the top of the extractor to flow through a dryer (a desiccator), in order to purify it and remove
179	any excess water content. The extraction was carried out at a steady state with a solvent
180	feed ratio ranging from 5–20 ml. The solvent was removed through the column at a rate of
181	200 – 450 ml per minute.
182	3.1.3 Separation and quantification of bio-butanol
183	The separation and quantification of bio-butanol produced by Clostridium species were
184	carried out by Gas Chromatography and Mass Spectrometry (GC & MS) as described by
185	[13]. One microliter (1.0 µL) of acidified sample was injected into "Schimadzu GC-14, Gas
186	Chromatograph" equipped with flame-ionization detector.
187	The column used for the separation of solvent was PEG (2.1m x3.0mm). The temperature
188	programming of the column oven was 60 °C/min. One hundred and twenty degrees
189	centigrade (120 °C), Nitrogen gas (30 mL/minutes) was used as carrier gas. The
190	temperatures of injector and detector were 150 °C and 200 °C respectively. The Peaks were
191	recorded on "SHIMADZU C-R-4_A, Chromatograph", and were identified by comparison of
192	the retention times with that of standard mixture. The experiment was carried out in
193	duplicates and the means ± standard deviations of the yield of butanol were recorded. The
194	standard calibration curve presented was used in calculating the concentration of bio-butanol
195	produced by the various <i>Clostridium</i> isolates.
196	3. Results
197	The species of Clostridium that were isolated from soil in Keffi were identified using Cultural,
198	Morphology and different biochemical test as given in table 1. The three species of
199	Clostridium isolated from different location in Keffi was able to produce bio-butanol after
200	screening for bio-butanol production at pH 5.5, temperature of 37°C for 96hours were
201	Clostridium specie isolated from Old barracks produced the highest butanol 9.61± 0.94 mg/l
202	using sugar cane molasses and sugar utilization of 9.61±0.71 g/l and 4.8±0. 19mg/l using
203	waste paper substrate followed by <i>Clostridium</i> species isolated from Angwan Jaba 6.21±
204	$0.61 \text{ mg/l}$ , $9.05\pm1.11 \text{ g/l}$ of sugar utilization using molasses and $3.21\pm0.11 \text{ mg/l}$ using waste
205	paper substrate <i>Clostridium</i> isolated from Angwan kwara 5.48±0.99 mg/l and 10.11± 0.99 g/l
206	of sugar utilization sugar cane molasses and 1.97 ± 0.33 mg/l using waste paper substrate.

207	Mutation was induced in the Clostridium isolates and were identify using 16s rRNA as shown
208	in figure 1, 2 and 3 respectively. bio-butanol produced pH 5.5, temperature of 37°C for
209	72hours after the induce of mutation as given in table 2 using waste paper as fermentation
210	substrate shows that Clostridium species isolated from old barracks was C. acetobutylicium
211	also produce the highest butanol after mutation with 8.63±0.06 mg/l sugar utilization of
212	6.21±0.11 g/l followed by C. perfringenes isolated from Amgwan kwara 5.99 ± 0.31 mg/l,
213	sugar utilization of 4.89±0.19 g/l and <i>C. difficile</i> isolated from Angwan Jaba 3.01± 0.54 mg/l
214	and sugar utilization of 3.97±0.33 g/l respectively. Table 3 shows bio-butanol produced using
215	sugar cane molasses by the Clostridium isolates were C. acetobutylicium produced highest
216	16.63±0.06 mg/l and sugar utilization of 16.98±0.51 mg/l followed by C. perfringenes 14.19 ±
217	0.11mg/l sugar utilization of 12.99±0.06 mg/l and the lowest was produced by C. difficile
218	10.01± 0.01mg/l and 9.89±0.19 mg/l utilization of sugar respectively.
219	Figure 1, 2 and 3 shows the phylogenetic tree of the different species of the Clostridium
220	isolated from different location.

#### 4. Discussion

Butanol as fuel or blending component has some advantages compared to ethanol. For example a lower vapour pressure and higher energy density. The production of butanol in a microbial fermentation was first reported by Pasteur in 1861. Three different species of clostridium were isolated and identified using 16s rRNA from different location from soil in Keffi, were C. perfringens, C. difficile and C. acetobutylicium. This however, is not in contrary with studies earlier reported by [18] that Clostridium species are one of most common bacteria isolated from the soil environment. Bio-butanol production by different species of Clostridium isolated in this study is in agreement with other studies earlier described by [19, 20, 21] that Clostridium species are some bacteria that has the ability in production of bio-butanol. In the study it was observed that Clostridium species isolated from old barracks has the highest accumulation of bio-butanol at 37°C, pH5.5 after incubation of 96 hours.

Fermentation parameters and type of fermentation substrate play an important role in production of bio-butanol. It was observed that were was high production of bio-butanol

- 255 using sugar cane molasses and glucose which contain noncomplex sugar than using waste
- 256 paper which is made up of lignin which need to be detoxified to enhance the used of waste
- 257 paper in the production of bio-butanol to remove the inhibitor that will affect the growth of the
- 258 Clostridium isolates as earlier reported by [22]. In this study it was observed that the sugar
- cane molasses has higher yield of bio-butanol that when used in a media containing the
- waste paper, also base on the isolates that yield has the highest accumulation of the bio-
- butanol it observed that C. acetobutylicium has the accumulation of 8.63±0.06 mg/l in use of
- 262 waste paper as substrate and 18.03±0.17 mg/l on sugar cane molasses as substrate which
- 263 is agreement with work earlier reported by [18]. Also it was observed that there was increase
- 264 in the production of biobutanol after the isolate was expose to UV light for mutation which
- 265 suggested that for economical bio-butanol production using Clostridium species, Induction of
- 266 mutation will enhance the production of bio-butanol industrially

### 267

268 <mark>5. Conclusion</mark> 269

- 270 Clostridium species isolated from soil environment showed high capacity of production of
- 271 bio-butanol. It was observed that the use of both molasses and waste paper will be a good
- 272 source of carbon or media in the production of bio-butanol. Inducing mutation in *Clostridium*
- 273 species will help to overcome the challenges of using clostridium in industrial scale
- 274 production of bio-butanol.
